3. Toxic or infective dyspepsias, due to tissue poisons or to general or local infectious disease.
4. Irritative dyspepsias, due to stimuli originating in a local or distal organic lesion.
5. Mechanical dyspepsias, due to gross structural disease or to surgical modifications of the anatomy of the stomach.

In the first three of these groups, which probably comprised more than half the total cases seen even in consulting work, localized gastric pain was generally lacking, and certain symptoms were recognizable. Here the *x*-ray examination could not be regarded as essential. Some authorities suggested that all cases of chronic dyspepsia should be fully investigated. Even if feasible, he could not regard this as desirable, and it had the danger in a certain type of patient that it encouraged introspection, and led to a demand for yet further investigation. But as to groups 4 and 5, any case in which gastric or duodenal ulcer, pyloric or gastric stenosis or cancer was suspected should be submitted to careful *x*-ray examination of the stomach and duodenum. The stool should also be examined in these cases for occult blood, and if there was any indication for surgery the fractional test meal should be given. His conclusions were:

1. In all forms of gastric disease the clinical method, though not necessarily final, is most important.
2. In the majority of cases in groups 1, 2, and 3 given above investigation by modern methods is unnecessary.
3. In reflex dyspepsias due to extra-gastric lesions such as gall-bladder disease, radiological examination of the gall-bladder or the whole alimentary tract may be helpful and sometimes essential, but is only occasionally urgent.
4. In reflex dyspepsias due to active gastric or duodenal ulcers radiological examination is essential and urgent, and of the greatest value to the clinician. Stools should be examined for blood, and if *x* rays fail to confirm clinical symptoms a fractional test meal should be performed.
5. In mechanical dyspepsias due to pyloric or mid-gastric stenosis, gross and adherent chronic ulcers, the more serious after-effects of gastro-jejunostomy, and carcinoma ventriculi, radiological examination of the stomach and duodenum is essential, urgent, and of the greatest value, and examination of the stools and gastric contents should rarely be omitted.

In other words, in functional disorders due to general causes accessory methods were of little positive value; in functional disorders due to extrinsic organic diseases they were frequently helpful, and in structural diseases of the stomach the radiologist and the chemist had become indispensable.

The Value of Radiology.

Dr. Harrison Orton claimed that, with the improved apparatus now available, the *x*-ray examination was superior to all others in the diagnosis at any rate of organic gastric disease. Clinical examinations, he agreed, were extremely important, and biochemical investigation might be useful in certain cases. He need hardly add that the *x*-ray examination must be carried out by an expert of considerable experience. The evidence which such an examination could furnish might be divided into direct and indirect. By the former he meant the actual demonstration of the lesion, either on the screen or on a series of photographic plates; by indirect evidence he meant such evidence as could be obtained from the type of stomach, rate of emptying, and the nature of the peristalsis. Some years ago a good deal of importance was attached to this indirect evidence, but nowadays, with improvement in technique, very little reliance was placed upon any but direct radiological evidence, which, when the work was carried out by an expert, reached an accuracy not far below 100 per cent., even when the lesion was in an early stage. He gave figures of 135 consecutive cases operated on at St. Mary's Hospital after an *x*-ray examination. These included 52 cases of gastric ulcer and 51 of duodenal ulcer. In only three cases had the result of the *x*-ray examination been different from the operative findings; two of these could hardly be regarded as an *x*-ray error, and in the third the lesion was said to be at the pylorus when in fact it was on the lesser curvature. These figures, taken from one series only, confirmed his contention that in the diagnosis of organic gastric disease an *x*-ray examination was superior to all others, and as a single method of examination stood supreme. Dr. Orton then showed a series of lantern slides to illustrate the information which could be obtained from *x* rays as to the nature of organic gastric disease. One point brought out was the importance of examining the stomach radiologically in more than one position; in one case, in any but the prone position, the ulcer could easily have been missed.

The Fractional Test Meal.

Professor E. C. Dodds (whose paper was read in his absence by Dr. Robertson) described the examination of the stomach by means of the fractional test meal. Unfortunately, of recent years it had been the custom for many laboratories to hand over the passing of the tubes, the collection of specimens, and the bedside part of the fractional test meal to a junior, whereas in fact these were the most important part in the test-meal investigation. The technique consisted of three main stages: (1) the passage of the tube, the collection of the resting juice, and washing of the stomach; (2) the administration of the test meal and withdrawal of specimens at intervals of a quarter of an hour for two or three hours; and (3) removal of the contents of the stomach. Each of these stages was important, but the first was the most so. After a careful description of the technique charts were shown giving the findings in typical cases. Professor Dodds stated that it had been possible to obtain further evidence as to the origin of lactic acid. He and his fellow workers had succeeded in isolating lactic acid in zinc salt from a number of cases, and this had been examined polarimetrically and chemically. It was shown that the lactic acid in five cases was negative or racemic lactic acid, thus indicating that it owed its origin to fermentation, and was not laevo-rotary or sarco-lactic acid, as would be the acid produced through the action of animal cells. Zinc salt had been obtained from the gastric juice of patients both with malignant disease and benign conditions of the stomach, and in all cases the result had been the same—namely, a negative form of lactic acid. This all seemed to point to the fact that the lactic acid was definitely not pathognomonic of cancer, and the view that it was produced by the body cells must, he thought, be abandoned. On the general question Professor Dodds affirmed that the fractional test meal was of very great value in the diagnosis of gastric conditions. The test was essentially a clinical one, in which the chemical analysis was of minor importance. Any attempt to regard the test as one in which very accurate quantitative chemical analyses only would indicate the diagnosis was bound to lead to failure. After all, the interior of the stomach was the seat of very crude processes, where food was mixed up with saliva and gastric juice, and, if there were a carcinoma, with foul-smelling discharge and the products of stagnation. It was therefore rather futile to look to detailed chemical quantitative analysis for information of diagnostic importance. In any discussion as to the relative value of the fractional method, of *x* rays, and of other methods, it was essential to bear in mind the status of the person responsible for the tests. It was absurd to compare a test meal carried out by a student with an *x*-ray examination performed by the radiologist to a hospital.

General Discussion.

Mr. A. J. WALTON gave figures showing the proportion of positive results found on *x*-ray examination in various gastric and duodenal conditions in his experience. He pointed out especially the relatively low percentage of positive results with *x* rays in ulcers of the lesser curvature (176 positive results out of a total of 237 cases). The statement had been made recently that no type of gastric or duodenal ulcer ought to be operated on except in the presence of stenosis. That statement was based upon the claim that chronic ulcers were healed as a result of medical treatment, as shown by *x*-ray appearances. But the *x*-ray appearances were not an accurate record of the condition in the ulcer, and most of the cases reported in the press as having been cured by medical treatment had been watched for too short a time. He had no hesitation in saying that even in carcinoma—or perhaps he ought to say *especially* in carcinoma—the clinical history and the clinical investigations generally were of the utmost importance, and upon these the greatest stress should be laid.

Mr. H. W. CARSON feared that there was a tendency to cut short the detailed clinical examination of the patients in view of the fact that there were so many ancillary methods of diagnosis. He still believed that it was possible to discover by clinical investigation the definite evidence of alteration in muscle tone which gave a lead to the diagnosis of some pathological lesion. Taking a very thorough clinical history was one of the most important parts of the examination. With regard to ancillary methods, he favoured radiology. He could not say that he put the same reliance upon chemical examination as he did upon *x* rays. The *x*-ray examination, moreover, was of value when there was multiple ulceration, where the chemical examination was of no value at all. The *x* rays sometimes spared the patient an unnecessary and perhaps dangerous intervention.

Dr. G. W. GOODHART supported Mr. Carson in his argument for radiological examination. He confessed that he had been disappointed by the tenor of the discussion. The fact was that the majority of patients seen by the physician were suffering from neither ulcer nor carcinoma, but from functional dyspepsia. It was all very well for the experts to divide the cases up into groups as Dr. Ryle had done, but what the ordinary practitioner wanted was to be able to distinguish between the functional and the organic cases, and to know what tests could be of assistance in making such a division.

Dr. G. VILVANDRÉ, speaking as a radiologist, said that he was bound to agree that clinical investigation was the most important thing. Sometimes it was his misfortune to have a case sent for *x*-ray examination without any clinical notes or history having been forwarded. This was not treating the radiologist fairly. Every student should be taught to examine his cases in a careful clinical way. Radiology had its limitations. No radiologist could tell by present methods whether a penetrating ulcer of the lesser curvature was benign or malignant.

Dr. A. P. CAWADIAS agreed that the clinical examination came before everything else. Radiology and chemical examination might come afterwards to confirm, correct, and control, but they should never come before the clinical examination. With regard to these ancillary methods, he judged radiology to be the most important and to give the best results. The test meal, he thought, was declining in favour. It had never given positive results to be compared with those afforded by the *x* rays. It never revealed the whole function of the stomach. What it decided was not so much the gastric function as the endurance of the patient.

Dr. J. W. CARR described the case of a middle-aged man, suffering from illness of an obscure character, wasted, anaemic, and with an irregular temperature. There were no definite symptoms except loss of appetite. On examination nothing was to be made out except a possible slight enlargement of the spleen. There was no sickness. The man went into a clinic, and at the end of a fortnight a diagnosis was made, almost entirely by chemical examination, aided to some small degree by radiology, of malignant disease of the stomach, which was subsequently confirmed by operation.

Dr. W. S. C. COPEMAN thought that the fractional test meal had been given up in France and largely also in Germany, though this, of course, did not argue necessarily that it was of no use. But the answer which the clinician expected when he asked for a test of this sort was as to whether the stomach was reacting or not in a normal secretory fashion to the stimulus of food. The factors which controlled the actual hydrochloric acid present in the stomach must be very numerous, so that there was great liability to experimental error. What clinicians wanted was something which would give fewer variables, and he suggested that this could be found in the total chloride estimations. The normal limits within which the total chloride varied were scarcely wider than the free hydrochloric acid limits.

Dr. GEOFFREY EVANS was disappointed because the argument that evening had been so largely confined to organic disease of the stomach, whereas a very large proportion of the patients were suffering from functional dyspepsias. The diagnosis of these complaints should proceed along the ordinary lines that were adopted in organic disease, first an anatomical diagnosis as to the organ to which the disorder related, then a physiological diagnosis as to what sort of work that organ was doing. He thought that, proceeding on that basis, much valuable material was obtained by examination of the stomach and intestines by radiological and chemical means in addition to the clinical study. He rather deprecated the comparison of different methods; all had their value, and he thought it undoubtedly useful to examine radiologically a patient whose disease was purely functional, because this afforded help as to the shape and size of the stomach and its rate of emptying. Then as to test meals, although it was easier to examine the faeces than the secretion of the stomach, he thought test-meal examinations should not be decried. Perhaps at a future date some simplification of the method might be forthcoming.

Dr. RYLE, in the course of his reply, said that the test meal was of no value to him in the investigation of dyspepsias, other than those in which there was gross organic disease of the stomach. In functional disorders of the stomach, whether due to reflex upset or to an extrinsic lesion or other cause, the variety of result obtained by gastric analysis was such that he believed the method really not worth trying.

Dr. ROBERTSON, while feeling himself unable to reply for Professor Dodds, suggested that some of the criticism of the fractional test meal was based on a misconception of the technique and the time required.

Dr. ORTON closed the discussion by repeating the remark of a physician who came into the room where a patient was being dosed with tetraiodophenol-phthalein, and said, "One needs to be very robust to be a patient nowadays."

SURGERY OF THE SPINAL CORD.

IN the Section of Surgery of the Royal Society of Medicine on November 6th, with Sir HOLBURT WARING, the president, in the chair, a discussion took place on the surgery of the spinal cord.

Mr. HUGH CAIRNS, in opening, limited himself to tumours of the spinal cord and adjacent structures. The clinical course of the various types of tumour was well known. Pain was usually the earliest symptom, often aggravated by exercise, coughing, or straining of any kind. Patients would sometimes complain that their extremities were always cold. Stiffness of the legs, numbness of the feet, "creepy" sensations about the ankles, urgency of micturition during excitement, or a bout of pain were some of the other symptoms which might occur. Important evidence was obtained by lumbar puncture. Special stress should be laid upon the performance of Queckenstedt's test. The test might give positive results at a time when the cerebro-spinal fluid showed no change of colour. Jugular compression sometimes produced or aggravated root pains, corresponding to the site of the tumour. Surgeons were specially interested in the position of the tumour. Repeated sensory tests would give accurately the upper level of the tumour, but seldom its extent. Lipiodol should be used, not so much to diagnose the presence of a

tumour, as to explore its level in cases in which a tumour was known to be present. The lipiodol test was particularly valuable in cases where there was more than one tumour of the cord. Turning to treatment, Mr. Cairns said that the main object in the treatment of spinal cases was to get the patient to walk again. The process of recovery of the conduction of the cord varied remarkably in different cases. Sometimes recovery of function in the paralysed limbs began to be apparent a few hours after operation; in other cases it was delayed for weeks, but was eventually just as complete, and in still other cases the commencement was much longer delayed, even for years, and the recovery made very slow progress. His experience of the Breslau clinic, where apparently hopeless cases of spinal compression had been retained for long periods, up to ten years, and patients had begun to walk again for the first time even as long as six years after operation, had made him feel that no case of spinal tumour should be regarded as hopeless. The presence of adhesions and blockage of the subarachnoid interfered in some way with conduction, and this was of importance in treatment. Queckenstedt's test should be done as a routine after all operations on spinal tumours, for the subarachnoid space might still be blocked either because the removal was not complete, although it had appeared to be, or because of adhesions, or because of the presence of another tumour elsewhere in the spinal canal. Speaking of accidents at operation, Mr. Cairns pointed out that the cord was a most vulnerable structure, but it was now known that if proper technique and gentleness were employed, the patient whose cord had been exposed should not ordinarily show in consequence any depression of function. The type of damage at operation which produced severe disturbance to conduction was not of the nature of a clean incision; it was due to the pressure of forceps or gauze swabs, or undue traction on the cord during exposure or the removal of the tumour. He did not think the possibilities of surgery in the treatment of spinal tumours had yet been fully explored.

Mr. GEOFFREY JEFFERSON said that the principles of the operation on cord tumours seemed to him to be in general the principles of the treatment of spinal compression as a whole, and this was on so firm a basis as to allow of little discussion, the methods employed being more or less stereotyped. The results of a complete removal were often so good that no labouring of the point was necessary. With regard to diagnosis, it was a fact that the typical neurofibroma of the posterior root had as its outstanding symptom pain over quite a period of time. But pain of a root character was not the outstanding symptom of all spinal tumours. It was possible to get an impression of pain as an inevitable symptom which was not justified. On the other hand, it must be remembered that any unexplained pain might possibly be due to a posterior root tumour. He did not know of anyone who had been bold enough to operate for pain alone without interference with conduction, but one might occasionally feel justified in exploring, and might find a tumour in such circumstances. In cases of meningioma occurring from the posterior surface of the cord, the patients had pain, but it was not the leading symptom. He did not want to be made responsible for any view that spinal tumours were painless things; one had to recognize that pain was a leading symptom in a certain group of cases, but that in some spinal tumours it did not occur at all. Its appearance or non-appearance was governed largely by the life-history of the tumour and its position. With regard to lipiodol, there were quite a number of cases in the literature in which damage was supposed to have been done by this injection, but these did not bear a very close analysis. It was by no means clear that the damage was not due to the disease process. Lipiodol was very valuable for giving the exact level of the tumour if this was at all in doubt. He had heard it said by people that after operations in the mediothoracic region one was apt to get very severe vomiting, which caused the patient's death, and it had been suggested that this might be due to the upsetting of the vegetative centres which controlled the stomach. He had a strong suspicion, however, based on experience of two cases, that vomiting and death after operation might be due to uraemia. The blood urea should be taken in all cases of spinal tumour before operation.

Mr. A. J. WALTON said that very little was known about the cause of compression of the cord, and he thought it would be a long time before it could be definitely stated on a pathological basis what was the change which would lead to the inference that in the one case there would be a recovery and that in the other the prognosis was poor. He laid special stress upon the time of development of the signs of compression. The prognosis should be based absolutely on the time at which signs of compression developed. To the practical surgeon the important point was whether the cord had time to adjust itself to its new position. If there was a rapid development of the signs of pressure, the cord, as a conducting medium, was irrevocably ruined. He had always laid it down as a rule that if a patient had had an injury of the spinal cord and immediately developed a complete paraplegia, it was waste of time, and even a dangerous procedure, to carry out a laminectomy. The cord had gone, and gone for ever. If, on the other hand, there was a slow development, it was evidence that the cord had not been completely destroyed, and a laminectomy was justified. He wished to stress the importance of finding the level of the tumour. If he opened the dura and failed to find the tumour, realizing that it was higher, so that he had to take out bone after the dura had been opened, he did this further operation with care, but always with fear. It was a most practical point to be sure of the level of the lesion.

Dr. GEORGE STEBBING said that as a means of relieving pain in tabes he had tried antero-lateral section; relief had in a measure been secured, but there was recurrence some time after operation. He thought there was a wide field for this operation in cases of malignant disease, though he was not sure of its real value in tabes.

Dr. GEORGE RIDDOCH was of opinion that the importance of root pain could not be overestimated. It might not invariably furnish the exact site of the lesion, but in the majority of cases it did give an accurate indication of where the tumour was situated. With intermedullary tumours, of course, root pain might be absent, although pain of a different kind was not infrequently present. Mr. Cairns had referred to the work done by Sir James Purves-Stewart and himself, in which they had stressed the vascular changes as being the main cause of the paraplegia itself, and thus furnishing a reason why the symptoms might clear up very largely after the operation. In the course of that investigation very clear histological indications of this were discovered. He entirely agreed with Mr. Walton in laying stress upon the importance of the rapidity of compression as determining prognosis.

Mr. PATERSON ROSS said that when an extradural tumour was discovered it was not wise to leave the patient without opening the dura and making sure that there was no intradural projection. He related the case of a woman in whom a tumour was found lying in the extradural position. This was removed, so far as he could tell, completely, and yet, although the condition had been a slowly progressing one, the patient showed no signs of improvement, but gradually went downhill. On thinking the matter over carefully he came to the conclusion that it was possible there had been an intradural projection of the tumour which had not been seen, and in confirmation of this view he had a very similar case six months later. Here he found, inside the dura, connected by a sort of hour-glass structure, a portion of the tumour twice as large as that which was lying outside the dura. With complete removal this patient did perfectly well.

Mr. HUGH CAIRNS, in reply to the PRESIDENT, who asked if anything could be said about radium in tumours of the spinal cord, referred to some experimental work which he had done on this subject. Radon seeds, containing 10 millicuries, caused complete paraplegia to develop in a cat within five or six days; a larger dose caused a more rapid development, while with 7 millicuries it was a question whether paraplegia would occur. While small doses of radon could safely be applied close to the cord, large doses were definitely contraindicated, for while destroying the tumour they were likely to destroy the cord as well.

RETINITIS IN DIABETES.

At the meeting of the Section of Ophthalmology of the Royal Society of Medicine, on November 8th, Mr. CYRIL WALKER presiding, a paper was read by Dr. P. J. CAMMIDGE on "Retinitis in diabetes."

Dr. Cammidge said that retinitis of diabetics was described some seventy years ago, but there remained still some doubt as to the etiology of the condition. Earlier observers believed that the retinal changes were the result of an excess of sugar in the blood, but this view had been abandoned by most modern authorities, mainly on the ground that there was no constant relation between the incidence of the complication and the severity of the primary disease. The presence of albumin in the urine of many diabetics suffering from retinitis and retinal haemorrhages had suggested an alternative hypothesis—namely, that the eye changes were dependent upon concomitant renal defects. The blood analysis he had carried out showed that in about 20 per cent. of his cases there was a pronounced retention of nitrogenous waste products, but that in the majority the evidence of renal insufficiency was comparatively slight, while in about 25 per cent. of cases it was entirely lacking. It was therefore probable that, although renal defects were the primary cause of the retinitis in a small proportion of cases, and were possibly a contributory factor in the production of the condition in others, they were not an essential feature. Apart from persistent and intermittent hyperglycaemia, the most constant chemical abnormality in his experience had been a low calcium level in the fasting blood; distinctly pathological figures were obtained in all his cases except those where a retinitis of the "albuminuric" type with pronounced albuminuria and serious nitrogen retention was present. There was no evidence that the low percentage of calcium in the blood in typical diabetic retinitis was the result of an acidosis, and, although in some cases it could be accounted for by an excessive loss of lime salts in the urine or faeces, there were others which showed a normal faecal ash and a normal calcium excretion in the urine. The fact that retinitis was rarely met with in diabetics before the age of 35, and usually in patients who had suffered from a mild glycosuria for many years, probably had a bearing on the question, for such patients seemed to be particularly liable to arterio-sclerosis and calcification of the peripheral vessels. The vascular lesions had been shown to resemble closely those which could be produced in rabbits by prolonged feeding with cholesterol, and therefore it was not unlikely that the persistent lipaemia found with increasing frequency in elderly diabetics with the passage of time, especially when restriction of the carbohydrate of the diet had been compensated by a liberal allowance of fat, was the determining cause of the retinal changes. Possibly it was the cause also of the deficiency of calcium in the blood, since there was experimental evidence that the metabolism of calcium and cholesterol were related, a fall of calcium in the blood being associated with a cholesterol rise. The blood analyses he had made showed a low calcium and an excess of cholesterol in cases where the excretion of lime in the urine was not excessive, but a normal cholesterol and a low calcium where examination of the urine and faeces revealed an unusual loss of calcium by these channels, which seemed to indicate that the deficiency of calcium in the blood was not always due to the same cause. Whatever might be the exact origin of the condition in any particular case, there could be little doubt that the diminished coagulability of the blood consequent upon a lack of calcium was one of the factors, and possibly the most important factor, in the production of the local haemorrhages which were of such grave prognostic significance in diabetic retinitis. Further proof of this conclusion was furnished by the results of treatment, for it had been found that the administration of lime salts by the mouth in sufficient amount to maintain the calcium content of the blood within the normal range prevented the occurrence of local haemorrhages in simple diabetic retinitis, although not in retinitis of the albuminuric type. Control of the hyperglycaemia and glycosuria, either by diet or with insulin, had no effect on the tendency to local haemorrhage, but it brought about a rapid improvement in the vision of most patients. This, together with the fact that retinal haemorrhages sometimes occurred without previous symptoms in patients who had been sugar-free for long periods suggested that the changes interfering with vision and the haemorrhagic tendency were of independent origin, the former probably being the result of local defects directly induced by the diabetic state, and consequently yielding to anti-diabetic treatment, whereas the latter arose from generalized vascular changes which were not a direct result of the metabolic disturbances induced by the diabetes, and therefore required independent treatment. Dr. Cammidge gave a detailed account of sixteen cases in which it had been possible to make an exhaustive chemical analysis of the urine, blood, and stools. These cases included equal numbers of males and females; the ages varied from 38 to 73, the average being 62. There was a history of diabetes in the families of ten out of the sixteen. The duration of diabetes had varied from two years to twenty-eight years, the average being ten years. There was sugar in the urine of all the patients except one, and in some it was as much as 10 per cent. The single patient who had no glycosuria was sent to him with a six-year history of diabetes. Only four of the patients had a trace of acetone in the urine. In the blood there was, in three patients, the most extreme retention of nitrogenous waste products, and each of these three had an enormous amount of albumin in the urine. The blood calcium was low, except in the three patients with nitrogen retention. High blood pressure was common in these cases, the average being 174, but four patients had a blood pressure of only 150, and one of only 130, so that blood pressure was not uniformly high.

Dr. R. D. LAWRENCE said that his own hospital cases showed a considerably higher percentage of retinitis than Dr. Cammidge's: about 11 per cent. of the diabetics under treatment had definite retinitis. In the past there seemed to have been no real explanation of the essential factors. Many people, to judge from ophthalmological literature, denied that there was diabetic retinitis apart from arterio-sclerosis. This view laid too much emphasis on the vascular side. Everybody admitted that many patients with diabetic retinitis had high blood pressure and cardio-vascular and renal symptoms, but in many such patients these conditions were absent. It was rather new to him to hear so much emphasis placed on the blood calcium. This was not generally supposed, except in severe acidosis, to be low in diabetics. In the patients who showed no signs of ordinary arterio-sclerosis the real damage, he thought, was a peculiar form of injury to the endothelium of the vessels. In diabetic gangrene, in addition to the calcification in the mesial layer of the arteries, the typical, and in his view the most important, finding was damage to the endothelium. The other possible factor in the production of these exudates and haemorrhages would seem to be some change in the osmosis caused by hyperglycaemia. This was undoubtedly the cause of the production of cataracts in diabetes, and had been particularly noticeable since treatment by insulin was introduced in the swelling of the lens which might occur when insulin treatment was started. He added that of his forty patients only one was under the age of 50. This was a change produced in elderly persons by long-standing diabetes, and it was related to the damage of the blood vessels more than to the immediate presence of sugar.

Colonel H. A. LISTER mentioned that his experience in India, where diabetes was extremely common, was that the proportion of retinitis cases was higher than the figures furnished for this country. The same age periods were affected, making allowance for the fact that Indians aged more quickly than Europeans.

Dr. CAMMIDGE, speaking in reply, said that he had only quoted as cases of retinitis typical cases which had been actually sent to him as such. It was quite possible that his figures were low as compared with those derived from hospital practice. With regard to the etiology of the condition, it was difficult to come to any definite conclusion. He was inclined to think, with Dr. Lawrence, that retinitis was not due altogether to the sugar, but the oedema and similar conditions which interfered with vision were undoubtedly due to the sugar because they cleared up so rapidly under treatment, especially in these days when he

could give insulin. With regard to treatment, those who had diabetic retinitis were generally elderly folk, to whom —because any sudden or marked interference with the amount of sugar might have serious consequences—he had a strong objection to giving insulin if he could possibly avoid it. If elderly diabetics were treated by diet alone they were much more comfortable. With regard to low calcium, he generally gave calcium lactate, but as most of the patients had intestinal catarrh, he prescribed it in an emulsion of liquid paraffin. A start was made with five grains three times a day, and as soon as the blood calcium reached normal level the daily total could be reduced to five or seven grains. This, of course, was only a prophylactic measure. Lately he had been trying the effect of vitamin D, and in other cases of parathyroid, but without very satisfactory results. The important point so far as he was concerned was to point out that the ophthalmic surgeon who treated his diabetic retinitis for diabetes was not doing his best for the patient. The patient must also be treated for his low calcium.

TUBERCULOSIS AND PREGNANCY.

A meeting of the North of England Obstetrical and Gynaecological Society was held at the Liverpool Medical Institution on October 25th, with the president, Dr. G. W. FitzGerald (Manchester) in the chair. Mr. Leyland Robinson (Liverpool) read a paper on tuberculosis and pregnancy, which was based upon 200 answers received to a questionary submitted to experts in tuberculosis.

Mr. Leyland Robinson dealt with the effect of pregnancy on latent, quiescent, and active types of disease. He discussed the treatment, special attention being paid to the value of therapeutic abortion. The main conclusions arrived at were as follows. Childbirth is always a danger to the phthisical woman. All forms of pulmonary tuberculosis—latent, arrested, or active—are affected by parturition. In the interests of the individual it is desirable that reproduction by phthisical patients should be regulated. Sterilization is neither desirable nor probable. Special arrangements ought to be made in sanatoriums for the treatment of pregnant women suffering from tuberculosis, and adequate accommodation be provided for labour and the lying-in period. Phthisical women who are pregnant should receive the ordinary sanatorium treatment, including artificial pneumothorax. Therapeutic abortion had a limited field of usefulness, and should be restricted to special cases of early disease in early pregnancy. Special ante-natal supervision by a skilled obstetrician must be considered an essential part of the routine treatment. The child must be isolated. Lactation must be forbidden.

The President, opening the discussion, said that his impression was that tuberculous women improved during pregnancy, but grew rapidly worse in the puerperium. Dr. C. R. Schofield (Southport) stressed the difficulty in arranging for the care of a pregnant tuberculous woman. He had just had a case of a young patient who developed acute pulmonary tuberculosis and a tuberculous larynx within a month of term. Eventually he induced labour, but she had died in three months. He had seen some tuberculous mothers improve during and between pregnancies, and others who were killed by pregnancy. He considered that much depended on the stage of the disease. Dr. J. E. Gemmell (Liverpool) recalled a case of a woman who showed evidence of phthisis after a miscarriage. After several years of treatment she was declared cured on the evidence of the physical signs and x-ray examinations, and was allowed to become pregnant. At the sixth month the disease reappeared and she was dead in two months. Dr. W. W. King (Sheffield) mentioned a case which improved during pregnancy and rapidly went downhill after delivery. He emphasized the importance of remembering the diversity of tuberculous disease. He cited statistics from an American hospital showing that in comparable cases under comparable conditions only 3 to 4 per cent. more pregnant than non-pregnant women showed advance in the disease.

Dr. F. H. Lacey (Manchester) quoted figures from the literature showing that the mortality was very little higher in pregnant than in non-pregnant women; it was at its highest in the first six months after delivery. He considered that tuberculous disease of the larynx, or the presence of toxaemia, rendered the prognosis very serious. Dr. J. W. Burns (Liverpool) quoted a case of marked improvement during pregnancy under sanatorium treatment. Dr. P. Malpas (Liverpool) reported that in a recent German symposium the consensus of opinion was against the induction of abortion in all three stages of the disease. Dr. J. H. Willett (Liverpool) said that he had interrupted a pregnancy early where it occurred in a healed case.

Professor D. Dougal (Manchester) expressed the belief that Mr. Leyland Robinson's paper would become the standard one on the subject. He reminded the meeting that Dr. E. Rist of Paris (*Journal*, 1927, vol. ii, p. 247) considered pregnancy inimical to phthisis, and agreed with Coulaud, who thought the important factor was the hyperthyroidism which was associated with pregnancy. Rist, however, had highly commended artificial pneumothorax, and sanctioned marriage if the sputum was free from tubercle bacilli two years after this operation.

Sarcoma of the Uterus.

Mrs. Donbin Crawford (Liverpool) showed a uterine tumour for diagnosis. The patient was a 3-para, aged 34, who had last menstruated eighteen months previously, and had complained of pain in the lower part of the abdomen for the past nine months, which was becoming more severe. On examination the cervix was found to lie low in the vagina and to be softened; the body of the uterus could not be distinguished from a large soft swelling which filled the posterior and left fornices. There was no tenderness or bleeding on examination. The uterus, which measured 5 inches, was explored from below, but the finger perforated it, and so the abdomen was opened. The pelvis was found to be sealed off by omentum, and when this had been separated some blood and fragments of tumour were exposed in the pouch of Douglas. The enlarged retroverted uterus was lifted up and found free of adhesions, but the peritoneum on its posterior surface, and the parietal peritoneum in contact therewith, showed purplish mottling. The tubes and ovaries were normal and non-adherent. There were no adherent intestines, no secondary growths, and no enlarged glands. The tumour was found to have replaced the whole thickness of the uterine wall. It was composed of large multinucleated cells in such a loose framework that they appeared to be in spaces. Frequent haemorrhages and many primitive blood vessels were seen. The tumour cells had invaded the blood vessel walls. Mrs. Crawford suggested that the tumour was a mixed-celled sarcoma.

Dr. J. H. Willett thought the history was too long to justify a diagnosis of malignant change in the products of conception. He saw no evidence of perithelioma, and concluded that the growth was probably sarcomatous. Dr. W. W. King (Sheffield) said the cells reminded him of those of a vesicular mole invading the uterine muscle, but remarked that these cells were not usually seen in such large masses.

Hydatid Cysts in the Pelvis.

Dr. J. W. Bride (Manchester) described a case of hydatid cyst of the broad ligament. The patient who had had previous cysts in the liver and lung noticed a painless lump in the right iliac region. On examination an irregular hard mass was found in the right iliac region, and a cystic mass in the pouch of Douglas. Five days later acute abdominal pain developed with vomiting, pyrexia, a high pulse rate, and abdominal rigidity. At the operation a large cyst was discovered which distended the right broad ligament; it was suppurating, and had perforated its capsule. A smaller cyst filled the pouch of Douglas, and several cysts about the size of walnuts were seen in the omentum. To remove the cysts it was found necessary to perform supravaginal hysterectomy. The patient suffered severely from shock, but thereafter made a good recovery. Haematuria appeared on the third day, but examination of the urine for hooklets was negative.

Mr. A. McMurray (Chester) described a case of hydatid cyst in the pelvis. The patient was sent to him on account

of prolapse, and, on examination, the cervix was found to be protruding from the vulva and irreplaceable; a cystic swelling filled the pouch of Douglas. At the operation this mass was shown to be adherent to the uterus and rectum; it was easily separated from the former, but with difficulty from the latter, and when this separation had almost been accomplished the cyst burst and daughter cysts came out. The abdomen was carefully explored for a primary infection, but none was detected. Mr. McMurray added that the case had three main points of interest: there was no obvious cause for the infection; this cyst was either a primary one or one evacuated from the liver; it caused a prolapse. *Drs. J. E. Gemmell* and S. B. Herd (Liverpool) both recalled cases in which hydatid cysts of the pelvis had obstructed delivery.

Acriflavine as a Perineal Dressing.

Mrs. Dorrin Crawford read a note entitled "A useful perineal dressing." After trying many dressings for perineorrhaphy and colporrhaphy wounds, she had come to use the following emulsion of acriflavine:

Acriflavin.	0.1
Paraffin. liq.	76.65
Cerae albae	3.25
Aq. destill.	20.00

Twenty-four to forty-eight hours were allowed to elapse, and at the latest on the third day, the day on which the aperient was given and before the bowels were opened, dressing was commenced with a narrow strip of gauze about three inches long; this was soaked in the emulsion, and by means of forceps laid upon the colpo-perineorrhaphy wound. The dressing was renewed after each act of micturition. The results had been satisfactory. The dressing had also proved itself of value after confinements in which there had been great bruising of the vulva. The author said that she had found the emulsion to be an ideal perineal dressing. The paraffin kept the perineum dry; the acriflavine kept it clean, or cleared up any incipient infection; while the whole was very soothing to the patient.

Dr. J. W. Burns (Liverpool) supported Mrs. Crawford's view of the value of acriflavine. In his experience a 1 in 1,000 watery solution had proved very useful for swabbing out an infected pelvis. He had also noted that it had a considerable haemostatic effect on an oozing surface.

GASTRIC AND DUODENAL ULCER: RESULTS OF TREATMENT.

At a meeting of the Liverpool Medical Institution held on October 31st, the proceedings took the form of a symposium on the results of treatment, medical and surgical, of gastric and duodenal ulcer.

Professor R. E. Kelly said it would be a mistake for the discussion to degenerate into that of medical *versus* surgical treatment of peptic ulcer. There was plenty of scope for both the physician and the surgeon. Each was apt to exaggerate his own successes and the other's failures. In actual fact surgical treatment was rarely undertaken without a preliminary resort to medicine, excepting, of course, in the urgent operations. He thought he could best help the discussion by a consideration of the difficulties. The greatest of these, he said, was the conflict of views regarding the etiology of ulcer. Neither hyperacidity nor Rosenow's streptococcus nor the chronic appendix was entirely satisfactory. He spoke of the difficulties in diagnosing the perforated and non-perforated ulcers, and suggested that from an anamnesis the duodenal could not always be distinguished from a gastric ulcer. He considered the pain of indigestion, including hunger pain, to be entirely muscular in origin. Mr. Kelly then gave an outline of what he considered the best technique in the operation of gastro-enterostomy. He thought the opening should be in the pyloric antrum, it should almost reach the greater curvature, and the vessels should be separately tied. Return cases often had the stoma far too much to the left, and showed a delay in emptying of over three hours. He related some cases of jejunal ulcer, and discussed the surgical problems of this perplexing complaint. He was in favour of a gastrectomy rather than a simple undoing of the gastro-enterostomy opening and a gastro-duodenostomy. For duodenal ulcers Finney's operation in his hands was not so satisfactory as a cautery excision and a gastro-enterostomy, and for gastric ulcers of the lesser curve he preferred a partial gastrectomy.

Mr. K. W. Monsarrat believed that the beginnings of gastric and duodenal ulcer always lay in a disorder of function which was set up in a variety of ways. The stomach developed a morbid habit and the resulting irritation might end in ulcer if the habit was not broken. He thought that the opposition of medical and surgical treatment was not intelligent. Apart from complications which required surgical intervention, he suggested that uncomplicated ulcer might reach a stage of chronicity when surgery was the only remedy likely to cure. The success of a surgical remedy depended greatly on the technique, and the general method was to remove the ulcer and to add to this a procedure which put an end to the gastric spasm and hypersecretion. He suggested that a detailed investigation of final results by a group of physicians and surgeons in Liverpool would be a valuable outcome of the discussion.

Dr. Henry Cohen urged that the ulcer diathesis should be recognized, in order that recurrence of ulceration after healing of an ulcer, whether by medical or surgical means, might be prevented by an adequate and permanent post-ulcer regime. Both medical and surgical treatment depended on a recognition of the associated factors, predisposing and exciting—for example, the acid factor, the infective factor (oral, nasopharyngeal, gall-bladder, appendix, urinary tract sepsis), and such accessory factors as tobacco, fatigue, cold, inadequate mastication, and so forth. He deprecated the use of any particular system of medical treatment, maintaining that each case must be considered on its merits, and the diet once established maintained until healing of the ulcer had occurred. He felt that routine medical or routine surgical treatment was a mistake. Cases should be considered in two classes: (1) curable by medical means, (2) curable by surgical means only. In the latter class he included perforations, cicatricial stenoses, ulcers with the slightest signs suggestive of malignancy, some cases of recurrent haemorrhage, and failure, after adequate trial, of medical treatment. He was not prepared to admit that the possibility of a gastric ulcer becoming malignant was such as to justify routine surgical treatment; the mortality from gastrectomy in the hands of the average surgeon, and the possibility of malignant disease of the stomach after such operations, negatived this line of action. In cases requiring surgical treatment, he thought gastrectomy in gastric ulcer, and gastro-enterostomy in duodenal ulcer, especially in cases associated with some degree of pyloric obstruction, yielded the best results. Stomal ulcers could be prevented in most cases by a proper post-ulcer regime.

In the course of a meeting of the Society of Public Analysts, on November 6th, Dr. Cuthbert Dukes read a paper on a new bacteriological test for pasteurized food. Dr. Dukes said that the idea underlying the test was that, when food had been pasteurized at a temperature of about 60° C., subsequent heating of the food to any temperature less than this would not appreciably reduce the number of bacteria, whereas heating above the pasteurizing temperature of 60° C. would considerably reduce the number. This was due to the fact that bacteria living in pasteurized food had already withstood, and could again withstand, the pasteurizing temperature. The mixed bacterial population of unpasteurized food, on the other hand, became reduced progressively as the temperature rose from 50 to 60° C. and upwards. When an examination was made of an unpasteurized food plentifully stocked with bacteria a heat resistance test of this kind revealed a great reduction in the number of surviving bacteria, and when these figures were plotted out as a graph a characteristic steep curve was obtained, representing the normal response of unheated food to the test. In the case of a pasteurized Cheddar cheese, on the contrary, the graph of the figures so obtained took the form of a horizontal line. A test based on these considerations was therefore useful to determine whether food had been pasteurized or not, and also the approximate temperature of any pasteurization which had been performed.

Reviews.

GASTRIC AND DUODENAL ULCER.

The fine monograph on *Gastric and Duodenal Ulcer*[1] by Dr. Arthur F. Hurst, and Professor Matthew J. Stewart of Leeds, with the co-operation of Dr. P. J. Briggs, is a striking illustration of the value of team work between a physician, a pathologist, and a radiologist who have long worked specially at this medico-chirurgical subject. In addition to the forms of ulcer mentioned in the title, which naturally take up nearly nine-tenths of the volume, there are accounts of jejunal and gastro-jejunal ulcers, peptic ulcers of the oesophagus, and tuberculous ulcers of the stomach and duodenum. The various chapters are headed by the name of Dr. Hurst or Professor Stewart, but each has consulted with the other, and so the contents represent their combined opinions to a greater degree than might at first sight seem to be the case. In a number of the chapters both their names appear as responsible, such as that on attacks and quiescent periods, perforation, subdiaphragmatic abscess, pyloric and duodenal obstruction, jejunal and gastro-jejunal ulcers, and peptic ulcer of the oesophagus. The generously and beautifully illustrated chapter on the radiological diagnosis is written by Dr. Hurst and his colleague at the New Lodge Clinic, Dr. P. J. Briggs.

When faced by all-round excellence it is difficult to pick out any one section for particular notice. From his wide experience Dr. Hurst has written the major part, and while leading the way in research has given admirable and most interesting historical surveys, not only in the opening chapter, where he reviews the whole subject, but elsewhere; for example, in the combined article on perforation there is the dramatic story of the Duchess of Orleans's death. His account of the pathogenesis is most complete, and includes the diathetic factor on which he has led the way; among the accessory factors he lays stress on the evil influence of tobacco, especially in duodenal ulcer. Professor Stewart's account of the pathological anatomy of gastric and duodenal ulceration is a monograph in itself, and represents his mature conclusions from many years' work on the ample material vouchsafed him at Leeds. At the outset he refers to the interesting occurrence of heterotopic gastric mucous membrane in the oesophagus, Meckel's diverticulum, and even in the ileum, thus explaining peptic ulcer in these situations. A special feature is the successful coloured plates. A later chapter on the pathology of ulcer-cancer or carcinoma arising in relation to a pre-existing ulcer, which must be distinguished from cancer-ulcer or simply an ulcerating carcinoma, is also illustrated by a coloured plate; his examination of ulcers excised at operation revealed that out of 70 cases of gastric cancer, 11, or 15.7 per cent., were ulcer-cancer, and that among 180 chronic gastric ulcers 11, or 6 per cent., showed carcinoma at the margin. Carcinoma in the cicatrix of an ulcer is, contrary to what might perhaps be anticipated, extremely rare, for he has examined one case only. The account of the rare condition tuberculous ulceration of the stomach and duodenum, the last article in the volume, is also supplied by Professor Stewart.

The subject of treatment of peptic ulcers has been so much discussed, especially from the surgical standpoint, that special interest must attach to what Dr. Hurst has to say on this burning problem. In the first place, he believes that it can be both prevented and cured by adequate medical measures: but he points out how deficient medical treatment commonly is—for example, by neglecting the control of acid secretion during the night, by not continuing until healing is complete (a result easily determined by *x* rays and examination of the faeces for occult blood), and by neglect of instruction how to avoid recurrence.

[1] *Gastric and Duodenal Ulcer.* By Arthur F. Hurst, M.D.Oxon., F.R.C.P., and Matthew J. Stewart, M.B.Glas., F.R.C.P. With the co-operation in the Radiological Sections of P. J. Briggs, M.R.C.S., L.R.C.P. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Sup. roy. 8vo, pp. xviii + 644; 10 plates, 159 figures, 63s. net.)

The chapter on surgical treatment is headed by Bastedo's obiter dictum in 1922: "The internist can refer his failures to the surgeon in good condition for operation, but in what condition does the surgical failure come to the internist!" The rival claims of medical and surgical treatment have long been a bone of friendly contention, but cannot be settled by contrasting the results of average medical treatment with the statistics of leading surgical operators, or, it may be added, by comparing the results of medical measures in Dr. Hurst's hands with those of surgical treatment all over the country. In a broad-minded discussion of this important question Dr. Hurst mentions that the cases at the New Lodge Clinic, in which operative measures for gastric and duodenal ulcer (the latter being the more numerous) were found to be desirable, had an average duration of symptoms for ten years, and that in 65 per cent. the results of operation were entirely satisfactory; but he points out that, with improved education in the methods of early diagnosis and medical treatment, complications, such as pyloric obstruction and hour-glass stomach, demanding operation should seldom occur, and that eventually gastric surgery will be almost confined to gastrectomy for malignant disease. The unsatisfactory results of operative intervention are set out, and, as already mentioned, a special chapter is devoted to jejunal and gastro-jejunal ulcers.

As this monograph will be a milestone in the history of the subject, a brief reference may be made to a previous milestone—Lord Moynihan's monograph dealing with the pathology, clinical aspect, and treatment of duodenal ulcer in 1910; the symptoms were then shown to be so characteristic and the physical signs so often absent—for radiology did not then lend any assistance—that for an accurate diagnosis the history or anamnesis was sufficient, and there was not any need to examine the patient; though Lord Moynihan considered that the treatment of duodenal ulcer should always be surgical, he expressed the pious and prophetic hope, now made more easy of fulfilment by Dr. Hurst's directions, that some at least of the patients might be permanently relieved of their sufferings by a much stricter and more prolonged medical treatment. There is therefore agreement that medical treatment should be improved and prolonged, and how this can be carried out is one of the important lessons taught in this epoch-making monograph.

Humphry Rolleston.

A SYSTEM OF BACTERIOLOGY.

It has long been a reproach to British bacteriologists that no systematic work on their subject exists in the English language. True, we possess textbooks of a more or less elementary nature for the student, but no systematic and comprehensive survey of the whole subject written for bacteriologists. When it has been necessary to consult a work of this kind one has had recourse to foreign publications, and however good this may be for developing a knowledge of modern languages, it is not good for our national self-esteem. Although science knows no frontiers, a scientific treatise of national authorship is inevitably national in flavour, so that to be compelled always to consult foreign literature leads in the end to a false sense of values. It is therefore with no small feeling of satisfaction that we learn that *A System of Bacteriology in Relation to Medicine*[2] is being produced under the aegis of the Medical Research Council and published by H.M. Stationery Office. Dr. Paul Fildes, together with Professor Ledingham and Dr. E. Schuster, has borne the brunt of the work entailed in this undertaking, and to him and his colleagues we owe a debt of gratitude for their self-sacrificing efforts.

This work, when complete, will consist of nine volumes. It covers the whole field of medical bacteriology, and will contain, in addition, short articles on the economic applications of bacteriology, so as to enable the medical worker to familiarize himself with developments in fields other than his own. The object of the series is not encyclopaedic, but to provide a comprehensive survey written in such a

[2] *A System of Bacteriology in Relation to Medicine.* Medical Research Council. Vol. iii. London: H.M. Stationery Office. 1929. (Sup. roy. 8vo, pp. 413. Single volumes £1 1s. net; set of nine volumes £8 8s. net.)

way as to indicate clearly the lines along which fresh efforts should be made. Some hundred British bacteriologists are contributing to this *System*; all of them are writing on subjects of which they have special knowledge.

Volume iii is the first to be published. It consists of a somewhat heterogeneous assortment of subjects comprising the economic aspect of bacteriology, the bacteriology of water, milk, and other foods, soil bacteriology, bacterial diseases of insects and plants, *Bacillus pestis*, *B. tetani*, *B. botulinus*, the organisms associated with gas gangrene and food poisoning. We realize how difficult it is in a work of this nature to avoid grouping unrelated subjects in one of the volumes; and, after all, it is of no real consequence if this does happen, though it offends the orderly mind's sense of fitness. Why, for instance, should not the chapter on *B. pestis* have been included in volume iv, where it really belongs, along with *B. pseudotuberculosis rodentium* and the Pasteurella group? This is a minor point, however, and it may be said without hesitation that the account of *B. pestis* would be welcomed wherever it appeared, for it is altogether excellent. Dr. Petrie has a most pleasant style, and his critical survey of the achievements in plague research and the problems facing us is very good. The chapters on *B. tetani* and the organisms of gas gangrene both reach a high standard of excellence. This was to be expected, for Dr. Fildes and Dr. Muriel Robertson, who contribute them, are authorities of more than national repute in their respective subjects. Fildes's recent work on the bearing of reduction potential in the tissues on the germination of tetanus spores might have received more elaborate treatment. His observations appear to be of fundamental importance, and to introduce a new conception in immunity of possibly wide application. Those who look upon the anaerobes of gas gangrene as of little importance in civil medicine will read with benefit the remarks that Dr. Robertson makes on infection with anaerobic bacilli apart from wound gangrene. This question has received greater attention abroad, and adequate references to the literature of this subject are given. If it is said that these three chapters are the outstanding features of the volume, that must not be taken to mean that the others are not good; they are, and in particular the accounts of the bacteriology of soil and water by H. G. Thornton and H. Henry respectively are very good. It must not be forgotten, however, that it is vastly easier to write an article on a subject like plague in a hundred pages than to discuss the economic aspects of bacteriology in a tenth of that space. If, therefore, the chapter on the latter subject by A. C. Thaysen appears a little thin and sketchy, it must be remembered that this was almost inevitable.

There is a marked absence of illustrations in this volume. To some this may appear a definite drawback, but it is not really so. Identification of bacteria is rarely a morphological problem; in fact, it should not be. Bacterial species show considerable morphological variation according to the age of the culture, type of medium employed, etc., so that pictures of bacteria are worthless and misleading. The editors are to be congratulated on having avoided the expense of unnecessary illustration. The volume is well printed, adequately bound, and of convenient size.

ACUTE INFECTIOUS DISEASES.

THE fact that *Acute Infectious Diseases*,[3] by Dr. J. D. ROLLESTON, has reached a second edition within four and a half years is a matter of congratulation to author and publisher alike, and is also evidence that such a book is wanted. It is, as its subtitle states, a "handbook," and it still retains that convenient form. In the preface to the first edition, reviewed in our columns on January 24th, 1925, the author stated that the work was *mainly clinical* in character, and therefore most of its pages are devoted to descriptions of the symptoms of the various diseases, their prognosis, diagnosis, and treatment. Dr. Rolleston's long and intimate acquaintance with the infectious diseases of this country and his reputation as a writer are in themselves guarantees of an adequate and satisfactory accomplishment of these portions of the book, and in the new edition the reader will find all that he requires to know for ordinary everyday practice, brought well up to date, and set forth in clear and concise language. But, recognizing how well the clinical part of the work has been carried out, we are the more surprised to find that, while the descriptions of the causative bacteria and of the morbid *anatomy of the diseases are dealt with in some* detail, little is said about their pathology. It is true that the pathology of several of the infectious diseases is unknown; but in some of them, especially diphtheria and scarlet fever, rational treatment is based chiefly on what has been found out about the pathogenic action of certain bacteria. Yet no explanation is given of the nature of diphtheritic, and very little of scarlatinal, antitoxin; nor can we find references to Mervyn Gordon's important work on the virus of variola and vaccinia, or to Esther Harding's and Lewkowicz's observations on the causes of the circulatory failure in diphtheria, and of the meningitis in cerebrospinal fever respectively. Since Dr. Rolleston devotes a brief chapter to "Fourth disease," though he has grave doubts as to its autonomy, and another to "Erythema infectiosum," which has not occurred epidemically in this country and is rare abroad, it might have been well to refer also to glandular fever and to epidemic catarrhal jaundice, both of which diseases have been within recent years epidemic in these islands. It is always a question whether bibliographies are worth while in handbooks. We are inclined to think that if the lists of references to literature, printed in large type and occupying nearly twenty-seven pages, were replaced in the next edition by the information, omitted from the present one, to which we have alluded above, this would remedy a certain one-sidedness in what is in other respects an excellent work.

ST. BARTHOLOMEW'S HOSPITAL REPORTS.

THE sixty-second volume of *St. Bartholomew's Hospital Reports*[4] edited by a committee, of which Dr. Geoffrey Evans and Mr. Girling Ball are the secretaries, opens with in memoriam notices of three veteran members of the consulting staff: Sir William Church, who edited these reports for sixteen years, and undertook the not inconsiderable labour of compiling the index to the first twenty volumes in 1885; Sir Dyce Duckworth, described as a frequent rather than a voluminous writer, whose bibliography begins with a pamphlet in 1862 and ends with a paper in 1922; and Mr. A. E. Cumberbatch, whose appointment in 1882 as aural surgeon was the first made in any general hospital in London. A series of comparatively short articles on the dietetic treatment of nephritis, diabetic coma, spastic constipation, steatorrhoea, diseases of children, and pernicious anaemia provides a great deal of interesting material, among which Dr. Brewer's summary of the bad effects of liver therapy, such as thrombosis, gout, diarrhoea, and polycythaemia, may be mentioned. Professor G. E. Gask gives a compact account of diverticula of the duodenum, and Sir Charles Gordon-Watson writes with the authority of much experience on the treatment of rectal cancer by radium. The recent work on haemolytic streptococci is critically discussed by Sir Frederick Andrewes; and Dr. R. R. Armstrong in a well-written essay argues that air-borne infection is a possible source of puerperal sepsis, and that, as it is difficult to control droplet transmission of *Streptococcus pyogenes*, the ideal of complete prevention of puerperal sepsis cannot be confidently anticipated. The comparative physiology of the menstrual cycle is considered by Mr. Wilfred Shaw; Drs. J. Maxwell and W. A. Nicholson find that primary malignant growths in the chest have become more frequent since the war, quite apart from any increase in malignant disease in general; and the history of the hospital museum is told by Dr. T. H. G. Shore on the occasion of the publication of a new catalogue.

HEALTH OF BRITISH TROOPS IN INDIA.

IN *Army Health in India*[5] Lieut.-Colonel JOHN MACKENZIE, R.A.M.C., has compiled an interesting history of the slow and gradual development of sanitation as applied to the preservation of health of British troops in India. Hospitals for the sick have always been maintained, and treatment, probably fairly well up to the standard of the times, has always been provided for the troops, British and Indian; but sanitation, with its object, the prevention of disease, can hardly be said to have existed up to the middle of the nineteenth century. It was not so much ignored as unknown. It hardly occurred to anyone that medical advice could be of any use in such a project as the selection of a new cantonment, or that such advice, if asked for, would be any good. The classical instance of this, which has often been quoted, is the selection of the site of the cantonment for the British garrison of Lahore after the annexation of the Punjab. Various sites having been suggested and discussed, one day the commander-in-chief, Sir Charles Napier, rode with his staff a few miles out from the city of Lahore, and, suddenly halting on a level plain, gave orders that the new cantonment should be placed on that spot. So came into existence Mian Mir, which for half a century was one of the most unhealthy stations occupied by troops in all India, suffering especially from malaria. The change of name from Mian Mir to Lahore Cantonment effected no improvement. Modern methods of sanitation, chiefly the introduction of mosquito screens for hospitals and barracks, and the removal of as many of the troops as possible to hill stations during the most unhealthy months, have considerably reduced the sickness and mortality rates. The report of the Army Sanitation Commission of 1859, and Miss Nightingale's remarks on that report, both of which are freely quoted, give a vivid picture of the sanitary condition of Indian cantonments seventy years ago. The proximity to barracks of insanitary native bazaars has always been a great source of ill health among the troops. One curse of those days has almost been got rid of—drink and its effects. Cholera has practically disappeared, fevers have been diminished by antimalarial measures; but venereal diseases remain an almost insuperable problem—much has been done, but much still remains to be done. The first appointments of special sanitary officers for the troops in India were made in 1898, when three were appointed for the whole country. In 1902 the number had risen to five, in 1921 to eighteen. The first antirabic institute in India was opened in 1900 under Major, now Sir, David Semple. There are now at least

NOTES ON BOOKS.

THE September number of the *Annals of Medical History*[6] contains eight articles in addition to the editorial on the homes of John Hunter in London, which is a review of Dr. G. C. Peachey's recent Thomas Vicary Lecture, and other book reviews by the editor, Dr. F. R. PACKARD. The opening article, by Drs. E. H. Pool and F. J. McGowan, on surgery at the New York Hospital a hundred years ago, occupies exactly two-fifths of the number, and is generously illustrated; the portraits of Valentine Mott on the cover and of J. K. Rodgers forming the frontispiece belonging to this well-documented footnote to history. Four other articles deal with American subjects. Dr. W. S. Middleton gives an account of Philip Syng Physick, the Father of American surgery, who very unwillingly obeyed his father's injunction to enter the profession of healing. Some personal glimpses of S. Weir Mitchell, physician, scientist, novelist, and poet, are contributed by Dr. J. Madison Taylor, his associate and assistant. Dr. Carnes Weeks records the details of the life of David Ramsay (1749-1815) of South Carolina, who was a physician, patriot, and historian, and was murdered by a patient whom he declared to be insane both before and after he was shot. Dr. J. I. Waring recalls an incident in early South Carolina medicine—namely, a protest by the medical faculty there in 1755 that they were improperly remunerated, and the resulting correspondence in the lay press Sir Andrew Macphail's William Potter Memorial Lecture at the Jefferson Medical College, Philadelphia, on evolution and life, contains much attractive philosophy. Sir Humphry Rolleston contributes an interesting article on Samuel Johnson's medical experiences, and Dr. Wagoner describes, with illustrations, an Etruscan bronze figure showing dislocation of the hip.

Short Stories in Science,[7] by Mr. J. G. CROWTHER, is one of a series of books entitled "Science for You." It would appear to be a collection of articles written by a journalist for sundry newspapers, including the estimable *Manchester Guardian*. Its matter ranges widely, from frozen meat and abnormally developed Hindu mathematicians to the smashing of the atom and the organization of the universe. Apparently the author's object is to show that science becomes a material of literature when the writer's description of it stirs the imagination of the reader. The journalistic nature of the book is shown by the first article, wherein views on the universe are attributed to Sir J. H. Jeans, Dr. Jeans, Dr. J. H. Jeans, and Sir James Jeans.

Clinical studies on urobilin,[8] by OLAF BANG, is a volume published as a supplement to *Acta Medica Scandinavica*. The author has made quantitative studies of the excretion of urobilin, by Einar Larsen's method, in a large variety of clinical conditions. He has studied the variations that may occur in normal individuals, and discusses the normal limits of the concentration of urobilin in the urine, and the conditions that cause a pathological excess.

The work entitled *Sex in Civilization*,[9] edited by V. F. CALVERTON and S. D. SCHMALHAUSEN, consists of a collection of thirty-two essays by anthropologists, neurologists, psycho-analysts, alienists, lawyers, and sociologists who have made a special study of the problem of sex. The book is divided into six main parts, devoted respectively to sex throughout the ages, the role of sex in behaviour, sex in psycho-sociology, sex and psycho-analysis, the clinical aspects of sex, including birth control, and sex in poetry and fiction. In addition to the introduction of Havelock Ellis, the following essays deserve special attention: Sex in religion, by Dr. Robert Briffault; Should all taboos be abolished? by Professor William McDougall; Sex in education, by Harry Elmer Barnes; A criticism of Freud's theory of sex, by Dr. Abraham Myerson; The civilizing force of birth control, by Margaret Sanger; and The art of love, by William J. Fielding.

A German work of nearly 1,000 pages on the surgical treatment of children's diseases[10] is a distinct and weighty contribution to scientific literature. The authors are ERWIN GOHRBANDT, PAUL KARGER, and ERNST BERGMANN, the first and last being surgeons and the second a physician. This collaboration gives the book its special character and value. For it is much more than a mere surgical handbook; rather is it a carefully balanced general survey of disease in childhood, with particular reference to surgery therein. The book falls naturally into three parts. The miscellaneous topics dealt with in the first part include anaesthesia, diathesis, and blood transfusion. The second comprises a systematic account of the surgery of the head, neck, and trunk. The third and most important part is devoted to deformities and their orthopaedic treatment, and the surgery of the extremities. A striking feature of the volume is its thoroughness. Within its covers will be found a complete guide to minor surgery in childhood as well as ample considerations from the point of view of the general practitioner. There are good charts, diagrams, and photographs, and many pages of bibliography. The work as a whole represents a very considerable achievement.

In his inaugural thesis delivered before the Faculty of Medicine and Surgery at S. Paulo in Brazil, Dr. SAINATI gives an account of his experimental work with the poison of the snake *Lachesis lanceolatus* on rabbits before and after immunization against that venom.[11] He finds that the smooth muscle of the normal rabbit is strongly stimulated by the venom, while it has no action on the similar tissue of the immunized rabbit; and he produces evidence to show that the immunity is of the cellular as well as of the general variety. The book is illustrated by a number of muscle tracings.

THE RADIUM PROBLEM.

STATEMENT BY THE RADIUM COMMISSION.

The following statement, drawn up by the National Radium Commission, on the present position of the radium problem, has been forwarded to us by its Chairman for publication.

National Radium Supply.

The interest of the world of medicine and of the public at large has been stirred by the advances made in the last few years in the treatment of malignant disease by radium. The subject is of such pressing national importance that in March of this year the Radium Subcommittee of the Committee of Civil Research issued a report which led to the creation of the National Radium Fund, which now amounts to nearly £300,000, of which £100,000 was contributed by the Government. Subsequently two bodies were founded to deal with this problem—namely, the National Radium Trust and the Radium Commission. As a result a largely increased supply of radium will be forthcoming for the use of the medical profession in its campaign against cancer. It is well, therefore, that a preliminary survey should be made of the present position of radium in the treatment of malignant disease, in order to assess its proper value, without either taking an exaggerated view of its healing properties or underrating them.

Misleading Claims.

In this connexion the Commission would strongly deprecate such extravagant claims as were attributed to a member of the medical profession, addressing a recent meeting of an English medical society, to the effect that on a five years' average they had cures by radium in 60 per cent. of operable cases of cancer, 37 per cent. in borderline cases, and 28 per cent. in inoperable cases. In the opinion of the Commission, figures such as these can only be described as cruelly misleading.

The True Position.

The true facts of the position, as known to the Commission, may be summarized as follows. It has been proved for many years that radium has a powerful effect on various affections of the skin, and that rodent ulcer and cancer of the skin can usually be completely cured by its use. During the last few years the technique of radium therapy has been elaborated and greatly improved by the use of radium needles, or of "seeds" containing radium emanation (radon), which are buried in the tissues in or around the growth. Most of the work done in this country, so far, has been directed towards the treatment of cancer of the womb, the lower bowel, the breast, and the tongue and mouth cavity. It can be stated definitely that in the above-mentioned regions, as the result of long and hard work, of many trials and many errors, a big step forward has been made.

Encouraging as are the results already obtained, it must not be assumed that radium can cure all cancers, for this is not yet the case, and many problems remain to be solved. The attack on the primary growth is, in a sense, the easiest part of the task; for if the growth is accessible and radio-sensitive, if the radium is implanted in the right place, if the whole of the tumour is irradiated, if the dose is correct, and if the exposure is rightly timed, then one may expect the shrinkage and disappearance of the tumour. Radium therapy, however, if it is to be successful, must aim at destroying not only the primary growth, but also any extensions which may have formed in the neighbouring glands. In the course of the work one point that has come out quite clearly is that destruction of a primary growth, followed by its complete disappearance, does not generally affect the development of secondary growths, if these are already formed, any more than excision of a cancer of the breast by the knife will cure a patient if there are secondary deposits in the interior organs.

Importance of Early Treatment.

We must again emphasize the fact that treatment of cancer, if it is to be successful, whether it takes the form of surgical excision, the cautery, radium, or x rays, must be undertaken early, or before dissemination has occurred: and it must be reiterated that an essential part of the campaign against cancer consists in the education and intelligent co-operation of the public so that early diagnosis and prompt treatment may be secured.

Radium and Surgery.

The relative value of radium therapy in the treatment of cancer, as compared with surgical excision, is a difficult point to assess, for the reason that sufficient facts are not yet available. In the first place most of the available data concern cancer only in the regions of the body above mentioned, and secondly, we have not yet a sufficient number of cases, nor has sufficient time elapsed, to enable us to prepare statistics which will show a true and complete picture. One great point in favour of radium is that its use does not involve the risks and suffering associated with extensive and mutilating operations, which are so distressing to all concerned. The operation of introducing the radium is in itself a comparatively slight one, and while the radium is in position the patient suffers little if any discomfort. Under these conditions, and with good prospects of cure without mutilation, patients should be far more ready to consult their doctors, instead of concealing or disregarding their symptoms till it is too late for any form of effective treatment.

Cancer neither Infectious nor Hereditary.

It is perhaps desirable, at this point, to deal with two prevalent misconceptions. First, there is no proof whatever that cancer is either infectious or contagious. Secondly, there is no evidence that cancer is hereditary, except in one rare form of cancer of the eye. These fears, therefore, can both be dismissed.

Radium "Bomb" Treatment.

So far, the successes achieved have mostly been by means of superficial applications, by buried needles, by radon "seeds," or by the combination of these three methods. Little has been done, in this country, in the radiation of tumours from a distance by large quantities of radium—that is, by several grams at a time. This method is known as "distance radium therapy," or more commonly as the "bomb" treatment, because a large quantity of radium is placed in a container—the "bomb"—and applied in such a way that the radium rays may penetrate the affected area. We have not had, hitherto, sufficient radium to do much in this way, although in some other countries it has been under trial. It is, however, a method which urgently requires investigation, and a 4-gram "bomb" has just been secured by the Commission and installed at the Westminster Hospital, where patients are now being treated with it.

The Case for Radium.

To sum up, a good case has been made out for the increased employment of radium. A new weapon, and a powerful one, has been placed in the hands of the medical profession, though how effective it may be it is impossible, as yet, to say. Nor is it yet established whether patients

A second series were carried out in which white bread, obtained from the local bakery and containing approximately 2 per cent. of yeast, was compared with whole-wheat unleavened bread (*chapatti*), made from the rapidly grown Nilgiri wheat, which is of inferior quality. The experimental details in this series were similar to those in the first. The results are given in Table II.

TABLE II.—*Showing the Average Percentage Increase or Decrease in Body Weight, on the Fifty-fourth Day of Experiment, of Animals fed on Basal Diets of White Bread and Whole-wheat Unleavened Bread to which various Supplements were made.*

Supplements to Basal Diets.	Increase or Decrease in Body Weight: per cent.	
	White Bread.	Whole-wheat Unleavened Bread.
I. Nil	21.2	55.7
II. Vegetable margarine (*Cocogem*) (1.25 grams)	2.4	12.7
III. Butter (1.25 grams)	15.4	51.7
IV. Tomatoes and greens (*ad libitum*)	56.3	68.1
V. Tomatoes, greens, and vegetable margarine	47.2	91.5
VI Tomatoes, greens, and butter ..	51.7	97.3
VII Meat residue (10 per cent.)	39.1	65 9
VIII. Whole milk (2 5 c cm.)	71.2	80.5
IX. Whole milk (2.5 c cm.), vegetable margarine (1.25 grams)	49.2	102.1
X. Tomatoes, greens, and milk (2 c.cm.)	92.9	139.6

The results of this series show that in every instance whole-wheat unleavened bread, though made from wheat of inferior quality, was superior to baker's white bread as the basal article of diet for growing rats. It is clear that the amount of yeast used in the manufacture of white bread (approximately 2 per cent.) did not make the bread equal in nutritive value to the whole-wheat unleavened bread, and that no matter what supplement was made to the two breads wholemeal bread always maintained its superiority over white bread. The pernicious effect of *Cocogem* will be noted, especially in those diets having a low vitamin B content.

Although the results of the two series are not strictly comparable, for the reasons that the experiments were carried out at different seasons of the year and that the whole-wheat flour used in the one was of different quality from that used in the other, yet it will be evident from a careful study of the tables that the results of the two series are complementary.

It is outside the scope of the present note to analyse these results further; nevertheless, there is one point to which attention may be drawn, since it may have a practical bearing in regard to the dietaries of growing children. The point is this: when the diet contains a considerable amount of fat, in the form either of margarine or of butter, then it is essential that the vitamin B content of the food be proportionate to the amount of fat, otherwise growth is retarded. Vitamin B appears to be necessary for the utilization of fat; wholemeal of poor quality may not contain enough of the factor for this purpose.

The object of this note has been to advance "experimental facts," in regard to white and brown bread, which indicate clearly that, as the basis of diets for growing rats, white bread is inferior in dietetic value to the unleavened bread (*chapatti*) made from freshly ground wheat. The latter, with milk, milk products, vegetables, and fruit, constitutes the diet of certain races of Northern India who, so far as physical efficiency is concerned, are amongst the finest of mankind. Their children, invariably breast-fed in infancy, know no other bread than whole-wheat *chapatti*, which they begin to eat from the age of 2½ years onwards. It does not appear to exercise any irritating action on their intestinal tracts. If, as stated by Drs. McCance and Lawrence, "brown bread is far too irritating" to the intestinal tracts of some English children, may it not be that their intestinal tracts are at fault rather than the wholemeal?

PURIFICATION OF SWIMMING-BATH WATER.

THE report by Messrs. E. A. Sandford Fawcett and H. T. Calvert, and Dr. J. Alison Glover, on the purification of the water of swimming baths,[1] to which we drew attention in the *Journal* of October 26th (p. 773), is concerned with the methods by which pollution in swimming baths occurs, the validity of various tests which have been adopted to estimate the extent of pollution, the transmission of infection by the water of swimming baths, and the devices by which the purity of such water may be maintained.

SOURCES OF POLLUTION.

Dangerous contamination of swimming-bath water appears to be derived mainly from the persons of the bathers, records of epidemics caused by water polluted from other sources being very few in number. Contamination from surface drainage percolation, fallen leaves, dead animals, and so forth, occurs mainly in open-air baths, particularly those with unlined sides and bottoms. The green growths which often appear in such baths actually have a beneficial effect, their powerful oxygenating action serving to purify the water from organic pollution. So effective are they that in the ponds at Highgate and Hampstead, which are seldom emptied, chemical analysis has shown that little change in the water is produced even by a large number of swimmers. Dust and soot blowing in through the windows of baths (especially those which have been placed near refuse incinerators for the purpose of obtaining power and heat) form, when the water is at rest, an uninviting scum on the surface of the bath. Despite the fact, however, that this scum may contain considerable numbers of *Bacillus coli*, the pollution is significant aesthetically rather than hygienically. A large proportion of filth found in the water is carried in by the boots of bathers and spectators, the side paths of the pools are regularly used by the bathers, and as a result they are almost always covered with a water suspension of visible dirt, a considerable quantity of which is then transferred to the pool from the bathers' feet. The authors of the report suggest that this source of pollution could be avoided by so designing the bath-house that the entrances to the dressing-rooms from outside are entirely separate from the paths by which the bathers enter the water.

The costumes of bathers contribute largely to the *defilement* of swimming-bath water; on some costumes there have been found more than one million bacteria per square inch, though with proper cleansing the figure should not be more than 500. An adequate precaution is to wash a bathing costume thoroughly with soap in warm water, rinse it three times, disinfect it, and then let it dry completely. Even greater than the bacterial contamination of costumes is that of towels; the proper cleansing, disinfection, and drying of towels is therefore a matter of importance.

By far the most serious sources of pollution are the hair, skin, and mucous membranes of the bathers themselves. The polluting matter is of three kinds: particulate matter, including fragments of recently discharged mucus; matter in solution; bacterial pollution, which may be considerable even in waters which appear attractive. The material in each of these categories requires separate consideration: the first brings about rapid depreciation of the water, rendering it opaque, greyish-black in colour, and offensive in smell; the second may be less important, and in baths which are efficiently filtered and sterilized the soluble constituents may be increased considerably without affecting the usefulness of the water. These two together, however, may have the effect of gradually converting the water into a culture medium in which bacteria—the material in the third category—are able, at the temperature at which indoor swimming baths are usually kept, to undergo rapid multiplication. The first form of pollution soon demands its own remedy; the second can be considerably reduced by making it a rule that all bathers before entering the water must take a shower bath, and by enforcing the use of soap, followed by a thorough spray of clean water, this procedure would be rendered still more effective. The third, which is the most important, requires separate consideration.

[1] Ministry of Health. The Purification of the Water of Swimming Baths. London: H.M. Stationery Office. 1929. 1s. net.

Bacterial Contamination of Baths.

The following bacteria have been found in the water of indoor swimming pools: *Bacillus subtilis*, *B. prodigiosus*, *B. fluorescens liquefaciens*, *B. coli*, *B. pyocyaneus*, *B. enteritidis sporogenes*, *B. proteus*, *Staphylococcus pyogenes aureus*, *Staphylococcus epidermidis albus*, *Staphylococcus* and *Streptococcus salivarius*, and a Gram-negative diplococcus (Graham Forbes). In addition to these visible organisms, it is conceivable that "commensal" invisible viruses, such as the virus of herpes, and "commensal" protozoa, such as leptospira, might also be present. The bacterial counts have been found to vary widely according to the number and cleanliness of the bathers and the treatment to which the water has been subjected. In their own investigations the authors of the report have relied upon the count on agar at 37° C. for forty-eight hours, and the determination of the presence of *B. coli*. Dr. Graham Forbes, who followed the same procedure, states that in an examination of 42 samples from five large open-air artificial pools, which were not subjected to any process of filtration or chemical treatment, the average count on agar for 1 c.cm. of water was 950, the highest count being 200,000 and the lowest only 1. *B. coli* was found in 1 c.cm. in 19 of the 42 samples; in 5 c.cm. in 10 samples; in 10 c.cm. in 3 samples. It was absent from 10 c.cm. in 10 samples. In contrast with these findings the authors cite the results of an examination in 26 samples taken from two open-air artificial pools treated by continuous filtration and chlorination. From one bath 17 samples showed an average count of 50 in 1 c.cm., the highest having 500; in 10 of these samples the total count was below 10 in 1 c.cm. *B. coli* was absent in 12 of the 17, and in 2 of the samples it was present in 10 c.cm. Similar results were obtained by using water from the second bath. Dr. W. L. Malman[2] has shown that *B. coli* multiplies rapidly during the night in swimming baths, while streptococci do not; he suggests, therefore, that an estimation of streptococci by glucose and lactose broth forms a better index of pollution than estimation of *B. coli*. The conclusions of his paper are as follows: (1) *B. coli* content is not a universally reliable index of intestinal pollution in swimming pools; (2) streptococci are constant indicators of intestinal pollution; (3) *B. coli* do not necessarily indicate pollution or danger, although their absence is an excellent index of safety.

Transmission of Infection by Swimming-bath Water.

Evidence for the view that diseases are occasionally transmitted by the water in swimming baths appears to be convincing. The diseases thus conveyed fall into the following groups: gastro-intestinal infections, respiratory infections, skin infections, eye infections, and nasopharyngeal infections, of which the last two groups are by far the most important. The only recorded epidemics of gastro-intestinal infections transmitted by swimming-bath water were undoubtedly due to gross contamination of the water by sewage. The occurrence of respiratory infections, such as pneumonia, has occasionally been described, but probably prolonged immersion, overfatigue, and subsequent chilling—all factors tending to lower the resistance of the bather's body to pneumococci which he is already carrying—are more significant in producing the disease than infection by virulent pneumococci actually conveyed by the water. The skin infections—for example, furunculosis, scabies, ringworm, and pediculosis—are probably transmitted by towels, costumes, and seats, rather than by water, despite the fact that organisms potentially pathogenic to the skin are often found in polluted bath waters. One important exception is furunculosis of the external ear, which seems generally to be due to auto-infection following the retention of bath water by cerumen and skin casts in the meatus. Erythemata and rashes caused by chemicals used for purification have been described, but their occurrence indicates gross overdosage, which should never occur in a properly managed bath. Conjunctivitis, the most common eye infection transmitted in baths, sometimes occurs in epidemic form, though it is more commonly spread by towels than by water. Several observers have called attention to the occurrence in epidemic form of a condition of conjunctivitis associated with nasal sinusitis and catarrh.

Considering what facilities obtain in swimming baths for the spread of such infections as scarlet fever, measles, chicken-pox, and diphtheria it is remarkable how few authentic epidemics have been recorded. There seems to be equally little evidence incriminating the water of swimming baths as a medium for the transmission of cerebro-spinal meningitis. The meningococcus cannot survive long in cold water, and it has never in fact been experimentally isolated from the water of swimming baths. In the few cases which are alleged to have occurred after swimming it is probable that the children were aerially infected from some carrier outside the bath water. The authors suggest that for the prevention of this disease, and of other diseases that are generally transmissible by droplet infection, the proper precautions would be ventilation of the bath hall and avoidance of overcrowding in the dressing-rooms, as well as purification of the water.

[2] *American Journal of Public Health*, 1928, p. 771.

Nasal Catarrh, Sinusitis, and Tonsillitis.

Increased excretion of nasal mucus occurs as the result of prolonged swimming in cool water, even when it is pure. It is possible that in unhygienic baths a bather might get from the water a dose of sticky mucus sufficiently massive to infect him with a catarrh or tonsillitis, though probably the more usual event is that prolonged immersion, exertion, and chill bring on an attack of catarrh or tonsillitis in a bather already carrying the infecting organism. According to the authors, no epidemic of diphtheria has been ascribed to swimming-bath infection, though, theoretically, water-borne diphtheritic infection might seem possible.

Otitis.

In an article on the relation of ear conditions to bathing (*British Medical Journal*, August 17th, p. 296) attention was drawn to the frequency with which acute aural inflammation has been observed in persons who have recently bathed in a swimming pool, and it is interesting to note, therefore, that, according to the authors of the report under review, "it is the ear infections which give the chief gravamen to the charge of disseminating disease against swimming baths." The questionary of the American Special Committee on Bathing Places was issued to 2,000 practitioners and elicited details of 129 cases of otitis, 19 of mastoid disease, and 5 of meningitis, while records of two epidemics of middle-ear disease were considered by the committee to be "reasonably authentic." In this country aurists have ascribed epidemic waves of middle-ear disease occurring in hot summers—for example, 1921 and 1928—to swimming-bath infection.

The authors suggest four possible ways in which the water might be responsible for the development of otitis media: the water may be the actual vehicle of infection transmitting the germs from one bather to the middle ear of another; it may act simply as a mechanical agent whose pressure forces already infected mucus from the nasopharynx up the Eustachian tube; the "insult" of cold water to the delicate mucous membrane may be sufficient to upset the drainage of the middle ear; and, finally, the etiological factor may simply be lowered resistance brought about by chill and fatigue. Probably the most important cause is hydrostatic pressure whereby pathogenic germs (particularly haemolytic streptococci) already carried by the patient are forced into the middle ear. The really extraordinary thing, the authors insist, is that there are not more cases reported, considering the vast number of persons who use swimming baths.

Methods of Purification.

All public swimming baths should be filled with water which is not only clear, sparkling, and attractive, but is practically free from pathogenic bacteria, or bacteria of excremental origin. For the purification of swimming pools of artificial construction filled with water from the main supply the authors favour the method of continuous rapid filtration combined with continuous chlorination and aeration. This method has advantages over the fill-and-empty system, even when the refilling is done every day. When the bath is not refilled daily, the advantages of the continuous filtration-chlorination become overwhelming.

The remainder of the report is devoted to a detailed description of the processes of filtration and chlorination, and of the necessary plant. The concentration of free chlorine aimed at by this method is not less than 0.2 part per million of water, or more than 0.5 part per million. Water which has been efficiently clarified by filtration, and having this free chlorine content, will give bacteriological counts approximating to the standard approved for drinking water.

British Medical Journal.

SATURDAY, NOVEMBER 16TH, 1929.

THE NEW MOUNT VERNON HOSPITAL.

In a changing world institutions, like living organisms, must adapt themselves or die. They must acquire new functions when there is no more scope for exercising their old ones, and they must modify their structure so that the new functions may be fulfilled. When, as in the present age, an epoch of social evolution may complete itself in a few years, institutions which cannot rapidly and successfully adapt themselves to society's changing needs stand in danger of decay or of being swept out of existence. The modifications which have taken place in recent years in our voluntary hospitals to make them available for a class whose needs were catered for in other ways when these hospitals came into being are an example of such adaptation, but of adaptation attained less by modification of the original too rigid structure than by the acquisition of a new one. Here, however, the change has been gradual: no sudden mutation, but a continuous evolutionary process, starting with the admission of middle-class patients into the ordinary wards, and culminating in the erection of special blocks for paying patients.

The transformation of the Mount Vernon Hospital, at Northwood in Middlesex, has been altogether more dramatic. The curtain fell on a hospital for the treatment of early tuberculosis; it rose on a hospital for the investigation and treatment under research conditions of malignant disease. The new function has been adopted because of its immense importance at the present time; the stimulus to its adoption has been the fact that the hospital could no longer exercise its old one. When in 1904 it received a large endowment for the purpose of determining the value of open-air treatment of pulmonary tuberculosis this therapeutic procedure was in its infancy, and the demand for treatment at Mount Vernon was correspondingly great. By 1927, owing to the vastly increased facilities throughout the country for the sanatorium treatment of persons suffering from tuberculosis, it had become obvious, both because the number of patients resorting to the hospital had greatly diminished, and because even these were suffering from disease too advanced to benefit from open-air treatment, that the main reason for which the hospital had been founded had ceased to exist. Here was an opportunity for the exercise of courage and imagination, which the governors were not slow to take. They decided to divert the activities of the hospital into an entirely new direction, and to devote all its resources to the investigation of malignant diseases and to their treatment under such conditions that the value of each method of therapy might be scientifically assessed. Their decision received the blessing and approval of the British Empire Cancer Campaign and the Medical Research Council, and they accordingly closed down the hospital buildings, and, to make them suitable for their new function, had them reconditioned throughout.

In our country, when revolutions become necessary we prefer to carry them through in a constitutional manner, and to this end there exists appropriate parliamentary machinery in the form of Enabling Acts; this machinery had to be set in motion before the council of management of Mount Vernon Hospital could effect its change of policy, and an Act was passed, which became law on May 10th, enabling the council to use the present land, buildings, equipment, investments, and income of the hospital for any purpose incidental and conducive to the attainment of its new objects. A special committee has been appointed, including Sir Humphry Rolleston, Lord Dawson of Penn, Sir Thomas Horder, Sir Cuthbert Wallace, and others, to advise the council of management upon the staffing of the hospital, and on all scientific and medical matters, and to suggest to the honorary staff the forms of therapy and research that the hospital might undertake. The individual members of this advisory committee have a tenure of office for four years, with eligibility for re-election after an interval of one year. The value of this provision lies in the fact that, whereas after an interval of one year an effective member of the advisory committee will not be forgotten, a member who has been unable to give sufficient time to his duties need not be reappointed. Still less security of tenure is offered to the members of the honorary staff. These have been appointed for one year only, but at the end of the year, and again at the end of each following year, they will be eligible for re-election. By this regulation each clinician will, so to speak, have to play hard for his colours: he will continue to hold office only so long as he is carrying out efficiently the investigations with which he has been entrusted; otherwise he will have to give place to someone else. No member of the staff, moreover, will have proprietary rights over a number of beds; it is intended that the clinical and laboratory staffs shall work together as a team, and the admission of patients will be regulated solely according to the needs of the hospital as a centre of investigation. Since the reorganization of the hospital the medical staff has been augmented by workers from other institutions, who have been chosen because of their interest and experience in the radiological treatment of malignant disease; in addition, there will be appointed a pathologist, a physicist, and a radiologist. The advisory committee recommends also that a medical director should be appointed, on a whole-time basis, to co-ordinate the activities of the hospital and to lead the team. With such aims and with a constitution so admirably designed to maintain the efficiency and enthusiasm of the clinical and laboratory staffs, the new Mount Vernon Hospital should attract to itself keen research workers from all parts of the British Empire. We are glad to note that clinical assistants will be appointed, and that the staff intends later on to give special courses of instruction in radiotherapy.

Although the Mount Vernon Hospital Act was passed only as recently as last May, already a considerable amount of work has been carried out, and 159 cases of malignant disease have passed through the wards. The investigations now in progress relate to the treatment of malignant diseases by means of radium and x rays; should, however, at any future time some other form of treatment show even better promise, then this in turn will be adopted and scientifically studied at the hospital. At present the more accessible diseases—for example, cancer of the breast, the mouth, upper air passages, oesophagus, the uterus, the rectum, and the skin—are being studied, but later on may be added cancer of the genito-urinary system, and of the stomach, intestine, and thorax. The results of treatment in each case will be carefully recorded, and the patients will be seen at frequent intervals for years after treatment has ceased. Diagnosis and

follow-up examinations will be carried out by the medical staff of the hospital at the existing London section in Fitzroy Square; this section will start work on January 1st, 1930.

The conclusions that may be derived from research work conducted by the Mount Vernon Hospital will be valuable in proportion to the number of cases the staff is able to study and the thoroughness with which they are studied. It is important, therefore, that the resources of the hospital should be used to the utmost, and that the full complement of patients—about 1,500—should be treated each year. To realize these ideals the hospital will need, in addition to its present supplies, about 2½ grams of radium; we hope that the council of management may succeed in obtaining this amount at an early date.

ERYTHRAEMIA.

OBSERVATION of the first recognized cases of splenomegalic polycythaemia soon made it clear that polycythaemia rubra ("polyglobuly") was not usually due to a mere condensation of the blood, but was a *polycythaemia vera*, the result of increased formation of erythrocytes in the bone marrow, and was accompanied by increase of the total blood volume; Cohnheim's teaching of the non-existence of persistent *plethora vera* had definitely to be given up. Vaquez's account (1892 and 1895) was followed after a few years by descriptions of cases in various countries, and Sir William Osler's writings (1903 and 1904) drew much attention to the *subject in England* and America. In post-mortem *examinations*—notably in the first really complete one (Parkes Weber and Watson, 1904)—the active red bone marrow was found enormously increased and the inactive fatty bone marrow correspondingly diminished, and this confirmed the view that the primary morbid process in the "Vaquez-Osler" splenomegalic polycythaemia was excessive blood-forming, especially erythrocyte-forming, activity of the bone marrow. Primary polycythaemia rubra was therefore termed "erythraemia," by analogy with "leukaemia"; and, by *analogy* with "leucocytosis," at the suggestion of H. Hirschfeld, the term "erythrocytosis" was adopted to include all classes of secondary true polycythaemia rubra—in which the increased formation of red cells was the expression of a *compensatory* reaction *on* the part of the bone marrow, as in the polycythaemias of high altitudes, congenital heart diseases, and obstruction in the pulmonary circulation of various kinds.

According to the *suggestion* of Professor A. E. Boycott in his recent presidential address before the Pathological Section of the Royal Society of Medicine, the total of the erythrocytes and their erythroblastic precursors may be regarded as a tissue-organ, which, like other tissues and organs, undergoes secondary hypertrophy or hyperplasia when the body requires it (*for* instance, at high *altitudes* or artificially low oxygen pressure), and hypotrophy or hypoplasia when fewer red cells are *needed* (for instance, when animals are kept in caissons under excessive oxygen pressure). For this tissue-organ the proposed term "erythron" may sometimes be convenient. In erythraemia the increase of the erythron appears to be *not* the manifestation of any secondary reaction, which from a modern teleological point of view could be regarded as *compensatory* or conservative, but to be of the nature of a diffuse *tumour* or *neoplasm*, which, though not *malignant*, must necessarily, by its inordinate growth, ultimately do harm to the rest of the body. In the rare cases of erythro-leukaemia or "Blumenthal's *disease*" the white *granulocytic* system seems to be involved, together with the *erythron* (erythrocytic system) in the neoplastic process.

Many neoplasms may be removed by the knife or by *x* rays or radium. Similarly, erythraemia may be treated by the application of *x* rays to the bone marrow,[1] *and*, though no surgeon would venture to treat it by operative removal of much of the erythroblastic bone marrow, the *safest method of* treatment, that by sufficient blood-letting, is really nothing less than operative removal *of* a superfluous part of the erythron, which *treatment* has *to* be periodically repeated, when, owing to the neoplastic process, the erythron *again* becomes excessive. Unlike ordinary new *growths*, the neoplastic erythron in erythraemic patients (as, indeed, the erythron in normal persons) can be partially destroyed by the relatively selective action of *a substance*—phenylhydrazine—administered through the mouth. Great care must, of course, be taken not to *administer* the drug in excess or for too long a period, as the destruction of red cells may continue for some days *after* the last *dose* has been given. It seems possible, however, that the liver cells in some cases may likewise become *damaged* either by the phenylhydrazine itself or by the products of the increased erythrocyte destruction.

In another part of our present issue (p. 892) Dr. Parkes Weber, who obviously favours the above explanation, describes and discusses a case of erythraemia accompanied by a variable degree of chronic acholuric jaundice, and by a blood plasma giving a highly positive, but indirect, Hijmans van den Bergh's reaction for bilirubin—that is to say, for "blood bilirubin," as distinct *from* the bilirubin that gives the direct reaction in the blood plasma in cases of ordinary obstructive jaundice. He is inclined to interpret the jaundice *in* that case as the manifestation of increased erythrocyte destruction in the spleen—an automatic attempt to compensate for the excessive production of erythrocytes in the erythraemic bone marrow. He also suggests that in the case in question the employment of phenylhydrazine to destroy erythrocytes and thus relieve the erythraemia might damage the patient's liver, possibly already overburdened as a result of the continual excessive destruction of erythrocytes in the spleen.

CLIFFORD ALLBUTT.

OUR readers will welcome very warmly, as we do, the publication of Sir Humphry Rolleston's memoir of Sir Clifford Allbutt,[2] his friend and colleague and predecessor in the Regius Chair of Physic at Cambridge. This short life of a great personality was undertaken, at the wish of Lady Allbutt, "with considerable anxiety"; and that it has been a labour of love, *in the fullest* sense of the phrase, no one can doubt. Clifford Allbutt was happy in his work, in his home, in his friends, and now he is happy in having as biographer a scholar-physician and a man after his own heart. To tell *in* 300 clearly printed pages the story of eighty-nine years of high achievement is no easy task. Much thought and research was needed to trace the milestones of a wonderful journey that began in the reign of William IV and went on without flagging until the night of

[1] For a recent paper on this subject see G. Milian, *Med. Assoc.*, 1929, xciii, p. 1295.

[2] *The Right Honourable Sir Thomas Clifford Allbutt, K.C.B., M.D., F.R.S.* By Sir Humphry Davy Rolleston, Bart. London: Macmillan and Co., Ltd. 1929. (With bookplate. 18s. net.)

21st, 1925. Much insight and literary skill was needed to resolve the elements of a many-sided but singularly harmonious character, and combine these again in a balanced portrait.

It is scarcely necessary to say of a book by Sir Humphry Rolleston that every page is packed with information—all of it relevant, concise, fully documented, and accurate to several places of decimals. In his preface he modestly speaks of this memoir as a "chronological record," and adds that so far as some of the earlier years are concerned it "has a bibliographical rather than a biographical character." True, his arrangement follows, though not too stiffly, the order of events; but by judicious choice of material and the introduction of apt and telling sentences from Allbutt's letters and published writings he continually brings the man before our eyes. In this and in other ways the record of an outward life of the utmost distinction is enlivened with glimpses of a very human and a very lovable nature. Moreover, the brief biographical allusions which abound in paragraph after paragraph give us an insight into the personal relations between Allbutt and a great number of well-known people with whom he came in touch during the several phases of his long career.

The whole work is informed with knowledge and sympathy, and a fine sense of what is fitting to be written of a great English gentleman whose mind and spirit never grew old. As an epitome of the man and his life-work it would be hard to improve on this passage towards the end of the last chapter: "In early life an original investigator both in the laboratory and in the wards, then a busy consulting physician, and after that for thirty-two years a Regius Professor with a world-wide reputation, he was throughout an independent thinker, a cultivated man of letters, and a philosopher; but greater even than these were the character and personal influence of the man who became the undisputed doyen of his profession in this country." Medical historians as such will find Sir Humphry Rolleston's volume a rich quarry of facts. All who knew Sir Clifford Allbutt will prize it most for other reasons.

SURGICAL CATGUT.

The manufacture and use of catgut dates from earliest times, though the first reference to its employment as a surgical ligature appears in the writings of Galen. Apparently it fell into disuse in surgery, and was not reintroduced until early in the nineteenth century, the credit for this rediscovery being given to an American, P. S. Physick, who studied in this country, and incidentally was house-surgeon to John Hunter. Contrary to what the name would imply, catgut is made from the small intestine of the sheep. This organ is removed immediately after slaughter, emptied of its contents, and cut longitudinally into strips or ribbons, which are then washed and scraped to remove the mucous membrane and muscular coat. The tunica submucosa alone is made use of, and these scraped ribbons are treated in alkaline baths, stretched, and, while still moist, twisted into cords of the requisite thickness. These constitute the raw catgut, which is now dried, disinfected, dried again, polished, and finally submitted to a surface sterilization. For surgical purposes, however, catgut must be rendered sterile throughout, and at first glance this might seem a simple matter. But it is far from being so, because in the first place catgut is peculiarly resistant to the penetration of antiseptics, and in the second place sterility is not the only desideratum. Sterilization must be achieved without undue loss in strength and suppleness, and the finished product must be capable of being absorbed in the body. Many have laboured to achieve this ideal, and the methods evolved have been mostly of the nature of a compromise in which absolute sterility has been sacrificed—not always wittingly—to the other qualities. In the history of our own country's contribution to this endeavour two names stand out pre-eminently—Lord Lister and Professor W. Bulloch. Lister's experiments extended over a period of forty years, and had as their result the carbolized catgut ligature in 1869 and the sulphochrome process in 1908. Professor Bulloch's researches stand in historical succession to those of Lister, and in this work he has been assisted by Dr. L. H. Lampitt and Mr. J. H. Bushill, of the research laboratories of Messrs. J. Lyons and Co. The results they have obtained are embodied in a report published by the Medical Research Council,[1] which will be welcomed not only as a record of the investigations of Bulloch and his colleagues, but also because it constitutes a most complete and interesting account of the history and literature of the subject. This work on surgical catgut has been carried out on behalf of the London Hospital Catgut Department, and it should be mentioned that the fruitful co-operation between Professor Bulloch and the research laboratories of Messrs. Lyons was due to the energies of the late Mr. Alfred Salmon, head of that firm and a member of the London Hospital House Committee. It would be impossible here to enumerate the different methods which have been advocated at one time or another for the sterilization of surgical catgut. In the report they are traced through the various "periods"—carbolic, sublimate, formalin, aseptic—down to the present iodine period inaugurated by Claudius in 1902. Each method has been thoroughly tested, and Professor Bulloch points out how essential it is completely to remove the antiseptic from the catgut before testing it culturally. It is the non-observance of this fundamental rule which has rendered much of the work on catgut of little value, and has been responsible for perpetrating inefficient methods of sterilization. From his searching inquiry he concludes that for the preparation of catgut on a large scale three methods alone out of many which have been devised can be considered as satisfactory—chemical sterilization by formalin or peroxide of hydrogen, and physical sterilization by heat. It is somewhat disconcerting to think that many brands of surgical catgut on the market are prepared by methods which have been found wanting in this investigation. Eight different makes of catgut ligatures were bought in the open market in 1927, and out of these 77 ligatures were examined bacteriologically; 58 proved to be infected. Thirty-six ligatures of another batch of catgut, also bought in the open market, were tested, and not one was found to be sterile. This is hardly a satisfactory state of affairs, and though the bacteria present were usually saprophytes, such as *B. subtilis* and *B. mesentericus ruber*, their presence indicates an inefficient method of preparation and a potential danger. Catgut infections in man have been reported from time to time, and cases of post-operative tetanus have been attributed to this source. Professor Bulloch submits the evidence of catgut infections to a critical examination, and concludes that they amount to little more than "clinical conjecture." Of post-operative tetanus he admits that there may be a suspicion against catgut, but that the facts do not allow one to go further than that. This does not mean that we should not insist on surgical catgut being sterile—far from it. Professor Bulloch's investigations have shown that such sterilization can be achieved by treating catgut with a watery solution of iodine. What effect has this on the strength and flexibility of the ligatures? This is where Dr. Lampitt and Mr. Bushill take up the story. They have investigated the effect of the reaction of the ribbon-baths

[1] Medical Research Council. Special Report Series, No. 138. The Preparation of Catgut for Surgical Use. By W. Bulloch, L. H. Lampitt, and J. H. Bushill. London: H.M. Stationery Office. 1929. 4s. net.

and of the method of spinning the washed ribbons on the strength of the ligature. Further, they have demonstrated the detrimental effect on the catgut of too prolonged an exposure to iodine, and the advantages which accrue from removing the iodine once sterilization has been procured. Finally, they indicate how the ligatures should be subsequently treated and stored in order to ensure flexibility and strength on the knot. In short, this report indicates how the ideal catgut ligature, at once sterile, supple, strong, and absorbable, can be prepared, and it is a matter of great satisfaction to read in the preface by the Medical Research Council that the licensing authority under the Therapeutic Substances Act has added surgical catgut to the list of controlled substances. The data contained in this report will be of the greatest assistance to those responsible for carrying out this measure, and the surgeon and his patient will have the assurance that what purports to be sterile catgut is in reality so, and not a potential source of danger.

POSSIBLE RISKS OF THE CONVEYANCE OF DISEASE BY BLOOD TRANSFUSION.

In the history of attempts to benefit one human being with material derived from another, the fear of the conveyance of unsuspected disease has been ever present. There seems little doubt that in the early practice of arm-to-arm vaccination sepsis and syphilis were at times so conveyed, and that there was some foundation for the wild accusations current amongst those opposed to vaccination.[1] In later days, since human blood or serum has been used in medicine, there has arisen the possibility of danger, either from disease in the donor or from contamination of the material outside the body. Indeed, a German writer[2] has pleaded for "protection against protecting serum," the allegation being that the serum of a subject convalescent after measles had been bacterially contaminated after collection and caused the death of the child who was to have been protected by it against measles. Keynes[3] and Feinblatt,[4] in their monographs on blood transfusion, have collected instances of conveyance of malaria and of syphilis—one from son to father after transfusion—and of acute sensitiveness to horse protein transferred by the blood of an asthmatic. Several infections with syphilis in this way were discussed recently at a medical meeting in Paris.[5] Tuberculosis has been mentioned in the German literature, but in general this risk is probably small. Malaria would be an ever-present danger in tropical countries; here the donor's history and examination of the blood are indispensable. The chance of conveying syphilis from any patient with a positive Wassermann reaction, or, apparently, with even any history of a past attack, must always be borne in mind. The wise pathologist, when testing the volunteer donor's blood to establish the group, will always use the sample for other desirable tests. Feinblatt makes the interesting suggestion that where, after an emergency transfusion without previous examination of the donor, the blood is found to be positive in the Wassermann reaction, two intravenous injections of salvarsan, given as soon as is convenient, will protect the patient. The Health Department of the City of New York[6] has recently called attention to "the necessity of prompt action to curb dangerous and almost unbelievable abuses which have developed in connexion with blood transfusion." The department, therefore, proposes to establish an official list of donors, each of whom would have a passport in which his group and general certificate of good health on weekly inspection would be entered, as well as details of all transfusions. It is expected that the new service will be self-supporting. Keynes in 1922, when commenting on the tragic misfortunes that might happen, suggested "professional blood donors" under constant medical supervision. In London blood for transfusion has been mostly supplied by the rover scouts and volunteers from other similar organizations—persons of above the average health who have been glad to carry out this devoted service without reward or publicity. There is a small group of men employed about laboratories or hospitals, who might be called "professional donors," who give their blood for a fixed fee. Both groups are generally under the care of alert pathologists, and we cannot trace any record of any transfer of disease in this way in Britain. Vigilance is the handmaid of safety, and it is a matter for regret that a service on the lines of the London Blood Transfusion Service (British Red Cross) is known in only a few of the large towns outside London—for transfusion, now that experience has indicated its value and its limitations, has apparently taken a permanent place in therapeutics. From the conveyance of disease by the serum of patients convalescent after measles or poliomyelitis there is, under English conditions, but slight chance of trouble, for this work is generally in the hands of senior pathologists, whose experience would guide them in eliminating bacterial contamination and other possible dangers. Skin grafting, when it is necessary to use grafts from other patients, will usually be safeguarded in the same way as transfusion, for here, when establishing the compatible blood group, as recommended by Masson[7] and other writers, the obvious information can be gathered and tests carried out. Above all, the old common-sense rule indicates that one should always reject any person about whose robust health there is the slightest doubt.

OBSERVATION IN NATURAL HISTORY.

THE late Sir Rickman Godlee, in addition to his outstanding qualities as a surgeon, had a great interest in natural history; therefore it was appropriate that the second Godlee Memorial Lecture, delivered at University College, London, on November 7th, by Viscount Grey of Fallodon, should have had natural history for its subject. Lord Grey, who described himself as an amateur in natural history, and as one who was well aware of the distance which separated the amateur from the expert, delivered a lecture which charmed his highly distinguished audience. He began with some remarks on the very great difficulty of being accurate in describing, or perhaps in observing, natural phenomena. Accounts of the same occurrence by different people, all proceeding in good faith, were extraordinarily difficult to reconcile, though he agreed that an excessive caution was practised by the late Professor Alfred Newton, who, on being asked to identify the egg of a bird, would reply, "Bring me the bird which laid the egg, and I will at once identify it"! One long-persisting inaccuracy in natural history textbooks was as to the sounds emitted by waterfowl. What had been supposed to be the call note and the alarm note were now found to be simply the notes of the male and female respectively. Lord Grey spoke much of the robin, whose life-history was most perplexing and whose ways were perverse. In spite of long acquaintance with the robin—he had three in his garden who were accustomed to perch on his hand—he felt that naturalists were only at the beginning of their knowledge of this little warbler. A close study of birds, he thought, would show that their domestic life, at any rate as regards sexual behaviour, was more attractive and of a higher kind from the human standpoint than anything to be found among mammals. The lecturer went on to

say that he believed some of the theories of evolution and the survival of the fittest which had great vogue in the last century were now found, not indeed to be without basis, but to cover a much less extensive field than was formerly thought. When a theory was found to cover some of the facts there was a tendency to assume that it covered all, and to ignore facts which told in the opposite direction. In this connexion he mentioned the protective coloration of birds' eggs. The theory had obtained that colour, shape, and markings of eggs had a protective utility for the species. Some birds laid their eggs on stony beach, and the eggs were almost indistinguishable from the pebbles; others, like the woodpecker, laid their eggs in hollows where they were unseen, and laid white eggs—a confirmation of the theory on the negative side. But other birds, such as the redstart, also nested in hollows and laid eggs which might be supposed to be protectively coloured; while, on the other hand, the woodpigeon laid white eggs conspicuously in the open, and the thrush laid eggs which almost called attention to themselves, and the species still flourished. It appeared that while there were cases where the theory of protective coloration seemed to hold good, there were many others where the theory broke down. Much in nature did not seem to serve any utilitarian purpose, and had to be accounted for in some other way. The secrets of nature were still largely undisclosed. Lord Grey expressed his satisfaction that the somewhat sordid conflict between religion and science was receding. At one time the discoveries of science were advancing so rapidly that they seemed to be reducing the area of the unknown; but now, while scientific knowledge had vastly increased, the vista of the unknown, and with it the area of speculation, had enlarged yet more. Finally, Lord Grey spoke of the pleasures to be derived from the observation of nature, especially from the recurring seasons. At the same time, he was careful not to imply any criticism of those to whom beauty in nature did not appeal and who sought more artificial sources of enjoyment. "We must not erect our own pleasures into other people's duties."

SPECTACLES FOR VERY FINE WORK.

In our issue dated March 12th, 1927 (p. 483), we reviewed a report of the Industrial Fatigue Research Board on the effect of eyestrain on the output of linkers in the hosiery industry. In a report[1] recently issued this problem is discussed in relation to workers in other trades, and observations are recorded on the value of special spectacles to operatives engaged in very fine work. Certain industrial processes demand for their effective performance such clear perception of fine detail that illumination, however good, does not abolish the need for near vision, with its concomitant strain on the muscles of accommodation and convergence. Relief from this eyestrain can be secured without difficulty by the use of spectacles furnished with suitable lenses and prism corrections. Workers engaged in "linking" hosiery, in mounting lamp filaments, and in the weaving operation known as "drawing in" have almost unanimously expressed their liking for the spectacles, while their value has been objectively demonstrated by the fact that with but few exceptions their use has been associated with an increased output of work. The examination of fine steel balls for defects, such as cracks, flats, and pits, entails great visual strain; in this operation only workers with 6/6 vision are employed, and they are allowed frequent rests. By the use of glasses the hourly rate of output during the day was increased without any additional fatigue. In the weaving industry, woollen cloth, after it leaves the loom, is passed on for burling and mending; threads of the warp or weft may be missing, but the details can only be seen clearly when the eyes are brought very close to the material. Mr. Harry Lee of Leeds examined a dozen workers engaged in this operation, and prescribed suitable glasses; in every case a given amount of mending could be done in a substantially shorter time. From a purely economic standpoint, therefore, it is worth while prescribing glasses even to normal persons engaged in this kind of work. Dr. Wallace Henry of Leicester records further observations on the value of spectacles to linkers. The subjects of the earlier experiments have now used spectacles for three years without ill effect, and others in the same factory have recently adopted their use. Mr. E. B. Alabaster of Birmingham prescribed spectacles for workers engaged in filing fish-hooks, and found that the average hourly earnings of these workers were much higher after the glasses had been prescribed than they were before. Similar good results were obtained among those engaged in chevening, the name given to the process of working clocks on hosiery. Certain general considerations arise in connexion with prescribing suitable glasses for near vision; these glasses fog distance vision, and it is better, therefore, that they should be D-shaped so as to allow of clear vision over the lens. For some purposes the binocular loupes commonly used by eye surgeons and for fine dissections are recommended; these have small lenses, and are worn resting on the tip of the nose. The comfort of glasses, and the absence of unpleasant sensations, as of "drawing" the eyes, depend largely on the combination of suitable prisms with the spherical lenses. Many persons have latent insufficiency or excessive convergence at reading distance. In examining workers engaged on fine processes tests of muscle balance at six metres are not enough; the muscle actions must be tested at the working distance. It has been suggested that the use of these glasses by normal persons reduces the natural stimulation of the muscle, and eventually renders artificial aids imperative. Subjects of the experiments found, however, that they were able to do their ordinary domestic sewing in the evening as well as ever.

AN OSLER COMMEMORATION.

We share with our Canadian brethren their pride in the memory of William Osler, who was of not remote English descent, and whose greatest achievement, perhaps, was the introduction into North American medical schools of the English system of clinical teaching, which he elaborated and improved. It is too early, only ten years after his death, to guess at the niche he will ultimately occupy in the temple of medical fame, but we may be sure that it will be an important one. Textbooks—even the great ones, such as Watson's *Lectures on Physic*—are soon buried under the accumulated mass of later knowledge, but the impression made upon a man's contemporaries and juniors may endure much longer. Osler made no memorable contribution to medical knowledge and practice, but his gift of teaching, his kindly, tolerant nature, his humour, and his power of bringing men together to work in concert, will not soon be forgotten. We congratulate, therefore, the Canadian Medical Association on its action in setting apart a day of its annual meeting last June in Montreal in honour of Osler's memory.[1] On this day, which was officially called Osler Day, the Osler Library in the building of the McGill Medical School was thrown open to inspection, with all its treasures of medical literature. It had been intended that the first Osler Oration should be delivered by Dr. Francis J. Shepherd of Montreal, formerly dean and professor of anatomy at McGill, and a close friend of Osler's. Unhappily, Dr. Shepherd lived only to write the oration, but died

[1] The Osler Memorial Celebration. *Canadian Medical Association Journal*, August, 1929.

before the time of the meeting. The duty of reading his almost complete manuscript fell to Dr. H. A. Lafleur, another close associate of Osler's, who rounded off Dr. Shepherd's address with some of his own impressions and memories of his friend. The address consisted of a short description of Osler's career and an eloquent tribute to his personal qualities. Osler's cousin, Dr. W. W. Francis, who is the librarian of the Osler Library of 7,600 volumes, gave an interesting account of Osler's development as a bibliophile and the establishment of the Bibliotheca Osleriana. It is always a source of wonder to less industrious and less gifted persons how such men as Osler find the time to acquire the discriminating knowledge by which they are enabled to make such a collection of books. They would appear to combine within themselves some at least of the qualities of a Bernard Quaritch with the erudition of a Joseph Frank Payne. The collector's instinct is, indeed, not always associated with great intellectual qualities, and the bibliophile's interest sometimes stops short of the message contained between the covers of his precious tomes; but Osler was as much a reader as a collector. It is understood that funds have been collected in Canada to endow an Oslerian Oration, to be delivered every three years. The institution of this lecture bespeaks a worthy enthusiasm, yet we may be permitted to wonder what the hero of the occasion would himself have thought of it. Not the least of his charms lay in his sometimes impish humour, which might on such an occasion have prompted his *Doppelgänger*, "E. Y. Davis," to produce one of his characteristic satirical sallies. It was in the name of this same E. Y. Davis that Osler, as Dr. Francis tells us, produced an as yet unpublished paper entitled "The burrowings of a bookworm," with a quotation from which Dr. Francis concluded his account of the library: "I like to think of my few books in an alcove of a fireproof library in some institution that I love; at the end of the alcove an open fireplace and a few easy chairs, and on the mantelpiece an urn with my ashes and my bust or portrait, through which my astral self could peek at the books I have loved, and enjoy the delight with which kindred souls still in the flesh would handle them." These aspirations of E. Y. Davis, with their flavour of *Religio Medici*, have been followed as closely as possible in the arrangement of the "Bibliotheca prima," and Osler's ashes and his portrait repose among his beloved books.

A Royal Medal of the Royal Society has been awarded to Professor Robert Muir, M.D., F.R.S., for his contributions to the science of immunology.

The eighteenth volume of the *Wiener Archiv für innere Medizin* is dedicated to Professor K. F. Wenckebach on the occasion of his retirement from the chair of medicine at Vienna University.

An international society of orthopaedics has recently been founded on the initiative of Professor Putti of Bologna. A congress will be held every three years. The first will take place on June 5th, 1930, in Paris, under the presidency of Sir Robert Jones, with Professor Putti and Professor Gocht of Berlin as vice-presidents. The number of members has at present been limited to a hundred, of whom ten are British.

At a recent meeting of the council of management of the British Science Guild, the constitution of the Royal Commission on the Civil Service was discussed. Disappointment was expressed at the fact that, although the State directly conducts under its own management important and highly scientific and technical undertakings, the Royal Commission does not include a single scientific expert, or a man engaged in the application of science to the needs of the community.

AUSTRALASIAN MEDICAL CONGRESS.

THIRD SESSION, SYDNEY, 1929.

The third session of the Australasian Medical Congress (British Medical Association) was opened in the Town Hall, Sydney, on September 2nd, by Lord Stonehaven, Governor-General of the Commonwealth; between 2,000 and 3,000 people were present. In the course of his speech Lord Stonehaven spoke of the rapid progress made during recent times in the science of medicine, and warmly commended the part played by the medical profession in spreading civilization. He extended a cordial welcome to Sir Ewen Maclean, the retiring President of the British Medical Association, and to Dame Janet Campbell. The previous session of this congress had been held in New Zealand two years previously,* and eminent representatives of the medical profession there had now come to take part in the congress in Sydney. The presence of these distinguished guests was an indication of the reality of the links by which the Empire was held together. One such link was the British Medical Association, which was promoting team work in the conquest of disease, and had a record unsurpassed by any body of professional men. The Governor ended with an appeal that those who could should assist to the utmost of their financial ability in the encouragement and endowment of research.

The proceedings of the congress occupy two issues of the *Medical Journal of Australia* (October 5th and 12th), to which we are indebted for much of the information here presented.

President's Address.

Dr. G. H. Abbott of Sydney devoted his presidential address to a study of the great progress made in the treatment of disease in the last forty years. Since he started practice at the Royal Prince Alfred Hospital he had seen the carbolic acid spray pass out of use; the discovery of appendicitis, a curable condition which had replaced the dread diagnosis of "peritonitis," with its hopeless prognosis; the advent of gall-bladder surgery; the immense improvement in operations on the stomach and intestines; and the saving of innumerable lives by the introduction of diphtheria antitoxin. The president called especial attention to the advances in cancer research and the importance of early diagnosis. He commented pungently on the importance to Australia of improving the birth rate, and referred to the improvements introduced in New South Wales with regard to the prevention of maternal mortality and the promotion of infant welfare.

The Premier of New South Wales moved a vote of thanks to the president for his address, and touched on the valuable services rendered by Dr. Abbott as a distinguished graduate of the University of Sydney, a great hospital administrator, a successful surgeon, and a wise counsellor, who had always upheld the highest traditions of the profession. Sir Louis Barnett of Dunedin, president of the second Australasian Medical Congress, also joined in the tribute to Dr. Abbott, and spoke with deep regret of the death of Sir George Addington Syme. Sir Louis Barnett expressed the belief that these congresses would help to solve some problems of politics and economics, as well as those of science.

Gold Medal of the Association Presented to Dr. W. H. Crago.

The President then presented Dr. W. H. Crago with the gold medal of the British Medical Association in Australia, in recognition of the distinguished services he had rendered. Dr. Abbott recalled Dr. Crago's work on

* *British Medical Journal*, 1927, vol. i, pp. 584, 622, 670, 728, 773.

the Council of the New South Wales Branch since 1889, particularly as honorary treasurer from that year till the present time, with the sole exception of the year 1894, when he had been president of the Branch. Dr. Crago's great work for the *Australasian Medical Gazette* and the Australasian Medical Publishing Company has been previously noted in our pages from time to time, as also his immensely valuable contributions to the task of providing first one and then another house for the British Medical Association in Sydney. In many other directions Dr. Crago has lent his willing help, and, in short, as the president remarked, the history of the New South Wales Branch appeared to be practically the history of Dr. Crago's association with it.

Cancer Research in Australasia.

A meeting of the whole congress, numbering nearly a thousand, was held on September 3rd, with the president, Dr. G. H. Abbott, in the chair. Dr. F. P. Sandes (Sydney) opened a discussion on cancer research with a carefully reasoned statement of its present position and the developments which were contemplated in the future. He recounted the progress made in Sydney since the Cancer Research Committee had been appointed by the University in 1921, and expressed the hope that the whole Australasian organization might soon be unified more effectively than it was at present. Among other details mentioned was the establishment by the University of a radium emanation station and of hospital clinics; the University had received a sum of more than £130,000 during the seven and a half years of the campaign; moreover, the Commonwealth had provided an adequate supply of radium. Dr. Sandes then gave an account of the work going on in the various hospital clinics. At one of these alone during the last fifteen months more than 1,000 patients had presented themselves for examination, treatment, and inspection after treatment. About 500 patients had been submitted to deep x-ray therapy, and 800 to radium, with or without surgery. Dr. Sandes emphasized the importance of *promoting closer co-operation with investigators in other* departments of science, and stressed the necessity of free and frequent consultations between those engaged in cancer research. He reminded the congress of the educational aspects in cancer work, and recommended the members of the British Medical Association to do all in their power to spread authoritative information, as had been done in the case of venereal disease, tuberculosis, and *small-pox*. As regards treatment, surgery still remained the sheet anchor, but the University had now opened a laboratory for the preparation of colloidal lead, and had arranged for its distribution to hospitals and practitioners. In view of some lack of success which had attended this treatment, the Research Department was continuing careful experimental work. Further study was also necessary with regard to the basis on which the x-ray and radium lines of therapy were founded. He hinted that abstract speculation in physical science might possibly result in information which would serve to explain why radiotherapeutic measures sometimes failed and sometimes succeeded.

Professor Peter MacCallum (Melbourne) gave an account of the progress of cancer research in Australia, with special reference to the work in progress at the Walter and Eliza Hall Institute of Research in Pathology and Medicine, the Melbourne Hospital, the Baker Institute, the Royal Prince Alfred Hospital, and the Commonwealth Serum Laboratories. Dr. E. S. Meyers (Brisbane) read a contribution by Dr. Sandford Jackson, relating to the cancer campaign in Queensland. The Federal Government and the Queensland Government had each promised a subsidy of £5,000, and a number of committees had been appointed following the lines of those in New South Wales and Great Britain. An appeal was being launched for £100,000, and energetic steps were being taken to acquaint the public with the necessity for providing this sum. Reference was made to the degree of success attending the use of x rays, radium, and colloidal lead; the last of these had been abandoned. Dr. A. A. Lendon (Adelaide) described the progress made in South Australia, and Dr. I. R. Smith (Perth) read a statement by Dr. Bromhall, with reference to Western Australia. A new block of buildings was being erected in the grounds of Perth Hospital, comprising x-ray and radium departments. Reports were also received from Tasmania and New Zealand. The ensuing discussion ranged over the various points that had been raised, special reference being made to laboratory work.

MEETINGS OF SECTIONS.

Peptic Ulcer.

The first paper in the Section of Medicine was read by Dr. C. T. Champion de Crespigny (Adelaide); it was based on the examination of 802 patients treated at the Adelaide Hospital during four years, representing 2 per cent. of all patients admitted in that time. In the course of his paper he mentioned that, judged from the post-mortem findings, the frequency of this condition in the Mental Hospital was as high as 8 per cent. The etiology of gastric and duodenal ulceration remained a problem, but the speaker had observed a frequent association between ulcer and appendicitis. He believed that ulcers began acutely. Cancer rarely followed a gastric ulcer, and never occurred in a duodenal ulcer. Medical treatment should, he thought, be continued for three months, using either the methods of Sippy or MacLean. If, however, there was any suspicion of malignant disease, gross deformity and impairment of gastric function, duodenal ulcers with the retention of the test meal after five hours, recurrent haemorrhage, or deeply penetrating ulcers, surgical intervention seemed desirable. Dr. James R. Bell (Melbourne) discussed the statistical incidence of the various signs and symptoms in gastric and duodenal ulcer, with a view to assisting differential diagnosis. He concluded that such diagnosis depended mainly upon the association of a suggestive history with positive x-ray findings. Professor Hugh MacLean mentioned some etiological factors that might be concerned, and remarked that in Australia the conditions might differ from those in England as regards the seasonal incidence of peptic ulcer. He indicated some of the salient points in diagnosis, and devoted considerable attention to the treatment of this condition by a mixture of alkalis. He gave an account of the results of treating patients in this way at *St. Thomas's Hospital since 1923*, and concluded that the success obtained afforded a striking illustration of the value of suitable medical treatment. Dr. S. F. McDonald (Brisbane) urged the importance of considering the patients as well as the peptic ulcer, and submitted the possibility that some nervous disturbance might be concerned. Dr. H. A. McCoy (Adelaide) gave details of the use of radiology *in diagnosis, while Professor* A. E. Mills (Sydney) called attention to the value of a careful general clinical examination spread over several days. Dr. D'Arcy Cowan (Adelaide) reported a case to illustrate the necessity of after-care subsequent to an operation. Sir Louis Barnett (Dunedin) suggested that though there had been fewer operations at St. Thomas's Hospital during the last few years the pendulum might swing again in the direction of surgery.

Oedema.

Sir Richard Stawell (Melbourne) opened a discussion on oedema by calling attention to the problem of *determining* whether the persistence of fluid was due to a chronic defect of the kidney function or to an abnormal stagnation of fluid in the tissue spaces. He *considered* carefully the various factors in cardiac and renal oedema, including those of physical and chemical nature. He outlined the various methods of treatment which had been found useful in different conditions, and concluded that further investigation was *certainly* necessary. Professor D. W. Carmalt-Jones (Dunedin) devoted his speech to the etiology of oedema, and mentioned the part played by vitamin deprivation. Professor MacLean discussed the problem of the ability of the tissues to absorb fluid. Dr. J. F. Mackeddie (Melbourne) held that the albumin ratio had an etiological significance, and Dr. C. B. Blackburn (Sydney) stressed the value of *estimating* renal efficiency when confronted by oedema.

Protein Therapy.

Dr. Ivan Maxwell (Melbourne), in his opening paper on this subject, discussed the biochemical factors in protein therapy, with special reference to cutaneous tests. He pleaded for a more thorough course of pollen desensitization as a

prophylactic against certain forms of asthma and nasal sinus infection. Professor CARMALT-JONES discussed vaccine therapy, which he believed had not proved so useful as had been hoped. It was still valuable in expert hands, but was far from being foolproof. Great care had to be taken in obtaining the exact type of organism concerned. Dr. A. E. TAYLOR (Dandenong) condemned vaccine therapy as useless, and even harmful. Dr. B. M. SUTHERLAND (Melbourne) thought that the phenomena of hypersensitiveness constituted the important factor in diagnosis and treatment. Dr. C. T. CHAMPION DE CRESPIGNY (Adelaide) reported a case in which a girl, who was sensitive to egg albumen, had been desensitized, but the desensitization had only persisted for a short time. Dr. D'ARCY COWAN discussed the value of tuberculin, and urged the importance of giving large doses in suitable cases. Dr. K. HILLER (Melbourne) defended the use of vaccines, not only for prophylaxis, but also for therapeutic purposes.

(To be concluded.)

Nova et Vetera.

AN EARLY ADVOCATE OF EXERCISE IN THE OPEN AIR.

THE verses reproduced under this heading in our issue of November 2nd (p. 813) have already brought letters from Professor Karl Pearson, Dr. Parkes Weber, and others, throwing light on Dr. Jephson of Leamington, to whom the poem was "mirthfully inscribed." We have now received a good deal of further information from Mr. G. G. Bonser of Sutton-in-Ashfield, who has close family links with our profession, and seems to have specialized in Jephsoniana. As our readers now know, Dr. Jephson's name is still honoured in the town which he did so much to popularize as a health resort in the early part of the last century. The following biographical notes are extracted from an article contributed some years ago by Mr. Bonser to a local newspaper.

HENRY JEPHSON, M.D.

Henry Jephson was born on October 4th, 1798, at Sutton-in-Ashfield. In boyhood he showed a love of chemistry, and while experimenting with an explosive salt two of the fingers of his right hand were blown off. Despite this handicap he studied medicine at St. George's Hospital, and then went to Leamington (where he had previously lived for a time) as assistant to a Dr. Chambers. He was soon admitted into partnership, and became highly popular and successful. In 1828, however, he sold his practice and proceeded to Glasgow University, where he graduated M.D. After this he put up his plate at Cheltenham. "His fame was, however, so universal that a deputation of influential inhabitants of Leamington waited upon him, and finally induced him to return, and he purchased back his original connexion. Thenceforward his professional career was one of unbroken, brilliant success; he was literally besieged by eager patients, while a considerable portion of his time was devoted to gratuitous advice to the poorer class." In 1848 he became blind, and for twenty-six years his devoted wife waited upon him. She died in 1874, but he lingered on till May 13th, 1878.

Dr. Jephson was a munificent donor to the local hospital, and one of the founders of Leamington College; the restoration of the parish church and the preservation of the Pump Room were due to him. In fact, there was not a single institution in Leamington which did not share in his generosity. The Jephson Gardens in the centre of the town contain a marble statue, and the Pump Room a full-length portrait, both provided by public subscription; in the Town Hall there hangs a portrait, the gift of a grateful patient. His great success as a physician seems to have been due to his commanding personality and his rigid enforcement of regimen and diet. The Earl of Shaftesbury wrote of Jephson: "The very appearance of the man inspires confidence." A memoir appeared in the *British Medical Journal* of May 25th, 1878.

HANDLING AND STORAGE OF X-RAY FILMS.

RECOMMENDATIONS OF THE X-RAY AND RADIUM PROTECTION COMMITTEE.

ON a number of occasions recently we have considered some of the practical problems connected with the protection of hospitals from fire. The disaster at the Cleveland Hospital, Ohio, focused the attention of hospital authorities on the urgent need for precautions in the storing and handling of x-ray films, and it will be recalled that on June 8th (p. 1057) we published a letter from the British X-Ray and Radium Protection Committee embodying a number of simple suggestions to this end. This committee consists of representatives of the Section of Electro-Therapeutics of the Royal Society of Medicine, the British Institute of Radiology and the Röntgen Society, the National Physical Laboratory, the Institute of Physics, the Radium Institute, and the Universities of Liverpool, Manchester, and Edinburgh, under the chairmanship of Sir Humphry Rolleston. Its views, therefore, merit the careful attention of the authorities concerned in all the hospitals in this country. In the course of its letter the committee stated that, as further facts came to hand, it would pursue its investigations into the whole question of possible danger from x-ray films, and ultimately would draw up what detailed recommendations it considered advisable. The committee has now issued a thoughtful memorandum, in the course of which it reminds x-ray workers of the extreme rapidity with which the films in common use—namely, those of cellulose nitrate—burn when ignited. The burning of cellulose nitrate in bulk is almost explosive in character, and results, also, in the generation of large quantities of carbon monoxide and oxide of nitrogen, both of which are highly toxic compounds. Moreover, carbon monoxide is itself inflammable, and mixed with air may give rise to an explosion. It must be remembered, too, that celluloid will burn in the absence of air. The committee, while recording its view that the production and use in this country of satisfactory "safety" x-ray films should be encouraged, makes the following specific recommendations.

X-Ray Rooms.

In all rooms where x-ray films are handled and stored naked lights and open fires should be prohibited. Smoking should be prohibited in or near film cabinets or film stores. Films should not be placed near steam pipes, radiators, or the like. A ready supply of fire extinguishers, together with buckets of water and sand, should be available. The best means of extinguishing burning celluloid appears to be by the application of water.

Electric light installations should be of a permanent character; electric light bulbs in or near film stores or cabinets should be enclosed in strong glass globes. Generous ventilation should be provided, and, as recommended in para. 5 of the International Protection Recommendations, the plan of an independent exhaust fan in each room is to be preferred to a duct system common to a number of rooms. Doors should be arranged to open outwards, particularly from film-drying rooms and dark rooms.

The stock of x-ray films, whether unexposed or developed, should be kept down to the minimum. The stock of film records should be subjected to periodical drastic weeding out, and discarded films should be at once deposited in strong fireproof metal containers with self-closing lids, and destroyed at frequent intervals. They should not be placed in general refuse bins or burnt in a closed vessel. Stocks of unexposed films for immediate use, or current files of developed films, should be stored in cool and dry lock-up thermally insulated metal or hard-wood cabinets. Such a stock should not exceed a total of about 50 lb. (that is, about 1,000 12 in. by 10 in. films) distributed among several cabinets. Cabinets for unexposed films should be lead lined.

Developed films which are temporarily taken into hospital wards or theatres should not be left lying about in table drawers or cupboards, but should be kept in suitable metal containers. Such films should be returned to the x-ray department as soon as possible.

Film Stores.

Stocks of film exceeding about 50 lb. should not be stored in the x-ray department, but in a special, dry, cool, and well-ventilated room reserved exclusively for the purpose. The situation of the film store should not be such as to endanger the means of escape from any part of a building. The store should not be in the proximity of a lift-shaft or staircase-well,

or near an intake or outlet of a general duct-ventilating system. In no circumstances should it communicate with a general duct-ventilating system. Preferably the store should be an isolated single-story building with independent access. Failing that, the store may be placed on the roof of a building or, if that is not feasible, in one of the higher stories in as isolated a position as possible.

The walls, floor, and ceiling of the storeroom should be fireproof and of robust construction. The door should be fireproof and of a self-closing, closely fitting type. If the storeroom forms part of a main building, a useful further precaution is a fireproof vestibule with a second fireproof door. The store should be provided with a direct vent to the outer air, preferably on the side remote from the most adjacent building. Such a vent should not normally be less than a square foot in effective area, a figure which may require to be exceeded for large stores. The vent may be protected against weather, etc., by thin, unwired glass, or other equally frail device.

The store may well be equipped with steel cabinets. If it is designed to carry unusually large stocks of films (exceeding, say, one ton), it should be divided into completely isolated fireproof compartments, each with its own vent and fireproof door. The temperature of the store should be maintained at a moderate figure. If the roof is exposed to the sun suitable thermal lagging may be necessary in hot climates. It seems certain that good quality celluloid does not ignite spontaneously at any temperature attained under ordinary room conditions. The store should be equipped with an automatic water sprinkler device. If windows are provided in a film store they are best situated in a north wall, though other considerations may be more important. Any windows immediately above the windows or vent of the storeroom should be provided with wired glass.

THE MEDICAL WOMEN'S FEDERATION.

Council Meeting in Edinburgh.

The Medical Women's Federation held its autumn council meeting, from October 31st to November 2nd, in Edinburgh, where the members were hospitably entertained by the Scottish Eastern Association. The hall and rooms of the Royal College of Surgeons of Edinburgh were kindly placed at the disposal of the Federation, a favour which was much appreciated by all those present.

Among the subjects considered was a national maternity service scheme, which had been drawn up by a special committee, and which, with slight alterations, was accepted.

The dismissal of women from their medical work on marriage was discussed, and the opinion of the Federation was expressed in the following resolution:

> The Medical Women's Federation in council assembled expresses its firm opinion that marriage should not constitute a bar to the appointment of a woman to any medical post, nor should it be a cause for the termination of her contract. Her ability to carry out such contract should be the only deciding factor.

The inadequate salaries of the medical women in the employment of the Post Office were discussed, and it was reported that the Postmaster-General had consented to receive a joint deputation of the British Medical Association and the Federation, in order to hear their representations on the subject. The differentiation between the salaries paid to the woman deputy commissioner under the Board of Control for Scotland was also brought to the notice of the council. The work done by all the deputy commissioners is similar in every respect, yet the woman's maximum salary is considerably less than that of the men, and this maximum was reached by her in 1919. The male deputy commissioners appointed subsequently to herself have long since exceeded her in the matter of salary. Representations had been made in 1922, and again in 1924, but without any satisfactory result, and it is now intended to take up this matter with the Board of Control for Scotland once more.

Three new committees were appointed by the council: (1) a standing committee on national health insurance; (2) a committee for the promotion of an improved women's health service for India; (3) a committee to deal with the question of dysmenorrhœa among factory workers.

The council also passed a resolution requesting the British Medical Association to consider the desirability of suggesting to the General Medical Council that an additional representative for England be added, and stating the desire of the Federation to be associated with the British Medical Association in any representations which might be made on the subject. The council was of opinion that the great increase in the numbers of the medical profession, and the length of time since the last member was added, warranted the consideration of such an addition to the direct representatives of the profession on the General Medical Council.

Ireland.

Medical Register for the Irish Free State.

At the recent session in Dublin of the Free State Medical Registration Council there were present: the president, Dr. D. J. Coffey (nominated by University College, Dublin), Dr. H. F. Moore (nominated by the Executive Council), Mr. John Dundon (nominated by University College, Cork), Dr. Stephen Shea (nominated by University College, Galway), Dr. A. F. Dixon (nominated by the University of Dublin), Dr. E. Magennis (nominated by the Apothecaries Hall of Ireland), Mr. R. C. B. Maunsell (nominated by the Royal College of Surgeons, Ireland), Professor T. G. Moorhead (nominated by the Royal College of Physicians, Ireland), and Mr. M. R. J. Hayes and Dr. R. J. Rowlette, direct representatives. The president said that with the recent publication of the first *Free State Medical Register* and of the regulations for the procedure of the Medical Registration Council of Saorstát Eireann, the functions of the Council come before the medical profession, the qualifying bodies, and the public of the Irish Free State in ordinary routine. The privileges resulting from registration—namely, the exclusive right of the practitioners so registered to give legal certificates, to claim fees in their courts, and to fill public medical appointments—had been in operation since the establishment of the *Register* on May 26th, 1928, and he directed the attention of all medical students near the date of their final examinations to the need of registering when they qualified. The powers of the Medical Registration Council in reference to medical education and examination were also formally before their qualifying bodies. In respect of the powers affecting removal of names from the *Register* for offences coming within the provisions of the Medical Practitioners Act, 1927, the procedure proper to the exercise of such powers was embodied in the published regulations. There was here nothing that the medical profession in Ireland had not been familiar with previously in the procedure under the General Medical Council. While it was hoped and believed that the actual conduct of Irish medical life would need few occasions for the exercise of such powers it seemed proper now to direct attention to the obligation which was on the Council to discharge its duties in cases of conduct coming within the provisions of the Medical Practitioners Act. Such cases could only be presented, considered, and decided in accordance with the procedure which the regulations prescribed. Other powers of the Council indicated the status conferred upon it by the Medical Practitioners Act, in virtue of which questions of reciprocity with foreign countries and dominions might be considered and dealt with. Special relations existed with the General Medical Council in respect of right of entry in the British *Medical Register* on payment of the proper fees, as well as practical provisions as to the procedure in penal cases. He would add that the Medical Registration Council appreciated the fact that a large number of Irish-trained medical men permanently resident out of Ireland manifested their interest and appreciation of the establishment of their *Register* by taking all the necessary steps to ensure the registration of their names. In conclusion, Dr. Coffey expressed the Council's gratitude to the authorities of the Department of Local Government and Public Health for the facilities it had afforded to the Council, and to Mr. Wilfrid Brown, who had acted as registrar, for his able services in the preparation of the *Register* up to its establishment. Routine business in connexion with the *Register* was then transacted.

National Health Insurance Bill, 1929.

In moving the second reading of the National Health Insurance Bill, introduced in the Dáil on October 23rd, the Minister for Local Government and Public Health said that the bill was largely based on the findings of a committee appointed in 1924, which reported in 1927. That committee found that there was real benefit to the working classes through national health insurance. That fact was borne out by figures, for in 1928 a total of 21,250 persons received sickness benefit at a cost of £563,000. The bill

did away with the deposit type of contributor, and it was therefore necessary that the existing rights of societies to refuse or expel members should be withdrawn, except from societies founded for certain classes of persons. Under the existing law there was a contribution of 1s. 3d. per insured person for the treatment of tuberculosis, the administration of which was entrusted to county or county borough insurance committees. Half of the expenditure so entailed was recouped, with the result that there was a dual system of responsibility; the majority of insurance committees entered into agreement with local authorities, and transferred this portion of their funds in return for treatment in so far as money was available. The committees simply recommended certain insured persons for treatment, and the system gave rise to complaints. The bill suggested that the treatment of tuberculosis should be entirely in the hands of local authorities, and as a result these insurance committees would be abolished: The 1s. 3d. hitherto available and the fourpence available for the administration of the insurance committees would be transferred to the cost of medical certification. The committee had considered the question of the unification of approved societies and that of medical benefits. It was the opinion of the committee that unification of societies would be a more satisfactory way of dealing with the national health insurance scheme, possibly by way of better benefits and economy in administration. At the time the committee was sitting there were eighty approved societies, and at present there were sixty-five, so that this reduction had taken place since the committee sat. The committee was not prepared, however, to say whether unification was feasible; neither was the executive council. He intended, however, on the committee stage of the bill to introduce an amendment to give the House an opportunity of fully discussing the matter, with a view to improving the position. His amendment would take the form of authorizing the commissioners, in the case of voluntary amalgamation of societies during the next two years, to give a certain amount of compensation to employees whose services as a result of amalgamation might be dispensed with. His amendment would also provide that after two years the commissioners should have power compulsorily to amalgamate societies to a maximum number of twelve or fifteen for the whole State, and also to give compensation to employees as in the case of voluntary amalgamation, but granting no pensions. As to the question of medical benefits, the majority of the committee considered that there should be some such scheme. A great proportion of insured persons, however, received treatment already by the dispensary system throughout the country, and recently when boards of health were set up throughout the country it was thought that time would show what kind of scheme of medical benefits might be introduced. He personally thought that some system of medical benefits was very desirable. Dr. Hennessy (Dublin City South) expressed himself in favour of nationalization of administration rather than amalgamation of societies. He quoted figures showing that in the large cities the Poor Law medical service was inadequate for the needs of the people. He cited the case of a dispensary in Dublin where there were two dispensary doctors, who were euphemistically called "part-time doctors." Their average attendance on patients for any one of the past three years was: domiciliary 3,316, at the dispensary 19,944, making a total of 23,260. As each case would necessitate an average of four to six attendances, it meant that these two doctors made anything between 80,000 and 100,000 attendances. Their salary was £260 a year. In England, under the Insurance Act, no doctor could have more than 3,000 names on any one panel, and even that was considered too many. The medical profession favoured a national medical service in preference to medical benefits, because national medical service not only gave medical treatment to the insured man, but also to his dependants.

Treatment of School Children in Northern Ireland.

At the last meeting of the management committee of the Fermanagh County Hospital Dr. Kidd said there was a matter he wished to bring before it. As they knew, there was an arrangement drawn up between them and the regional education committee regarding the treatment of school children. Recently a child had been brought in for the removal of tonsils and adenoids. He had refused to perform the operation, and had therefore broken through the arrangement. He pleaded guilty to this, and asked the committee's indulgence. The reason he did so was that he did not consider that the child—the son of a retired merchant—came under the Act of Parliament as one who should benefit by State-aided medical service, and become a burden on the public funds. Dr. Kidd said he was entirely in their hands, but he mentioned the matter because it might be said, without considering the collateral facts, that he had taken the law into his own hands. He did so for the express purpose of bringing this whole matter to a climax at once. As he had said, it was only intended by the Act of Parliament that those who were necessitous should obtain benefit under its provisions. Such persons only pay 7s. 6d. to the regional committee, the remainder being paid out of public funds, and Parliament never intended that a man who had retired from business in comfortable circumstances should be able to have his child operated upon at the public expense, upon paying 7s. 6d. to the regional committee. He felt so strongly on this subject at the time the agreement was made that he went to the then secretary of the regional committee and asked that a reasonable income limit should be fixed below which parents would be entitled to have their children treated under the scheme. He did not claim any fee for patients who came there as ordinary hospital patients if there was some such limit fixed, and he considered his suggestion an eminently reasonable one. Mr. Dewane said that the trouble was that the agreement still stood. This child was attending a public elementary school, and the agreement was that all children attending public elementary schools should be treated irrespective of the position of their parents. A resolution regarding the agreement had been passed by the regional committee, and it was unfortunate that this incident had occurred, because the agreement would probably have been revised. Senator Porter said he thought that that committee would not sanction those with means being treated there as if they were paupers. Under the arrangement referred to in the above discussion patients repay or partly repay the cost of treatment to the regional committee. The chairman of the County Hospital remarked that he thought Dr. Kidd's attitude was correct.

Vital Statistics in Northern Ireland.

An important change has been made in the Registrar-General's seventh annual report for Northern Ireland, as was foretold last year would be the case. In his review of the mortality statistics for 1928 the rates have now been standardized by correcting them for the age and sex distribution of the population. The standard population adopted for this purpose is that of England and Wales in 1901, and since this population is also used as the standard by the Registrar-General for England and Wales, it is now possible to compare the death rates in the two countries. This having been done the fact emerges that during 1928 the death rate was 11.58 per 1,000 for Northern Ireland, as compared with 9.93 for England and Wales; an important feature of the Northern Ireland statistics is the relatively high death rate in the case of females. The corresponding figure in Northern Ireland for 1927 was 11.71, and for 1926 it was 12.26; the relatively low death rate in 1928 is mainly due to an appreciably smaller number of deaths from influenza, tuberculosis, and respiratory diseases, conditions which were responsible for the high rate in 1924. As a cause of death heart disease occupies the leading position, occurring mainly in persons of fairly advanced age. The figures are also relatively high for tuberculosis, cancer, pneumonia, bronchitis, and cerebral haemorrhage. It is noteworthy that there has been a slight decrease in the cancer death rate, which had shown an increase each year from 1922, with the solitary exception of 1926. The gratifying decline in the infantile mortality rate as compared with the previous three years is attributable to the fall in the rates from atrophy, debility and marasmus, bronchitis, and influenza. With very few exceptions the urban infantile death rates

were appreciably in excess of the corresponding rural rates; the number of births has fallen again, the figure for 1928 being 25,963, as compared with 26,676 for 1927 and 28,659 for the average of the last ten years. This implies that the birth rate, which was 21.3 per 1,000 of estimated population in 1927, has fallen to 20.8 in the year under review, which may be compared with the corresponding rate of 20.1 in the Irish Free State. The price of the Registrar-General's report is 2s. 6d.; it may be obtained from H.M. Stationery Office, or through any bookseller.

Scotland.

Honour for Glasgow Professor.

As briefly recorded elsewhere, the President and Council of the Royal Society have awarded a Royal Medal to Professor Robert Muir of Glasgow University for his contributions to the science of immunology. Professor Muir graduated M.A. at Edinburgh University in 1884, and M.B., C.M., with first-class honours, in 1888. He was for some years assistant to the professor of pathology in Edinburgh, and pathologist to the Edinburgh Royal Infirmary from 1892. In 1898 he was appointed the first professor of pathology in St. Andrews University, and relinquished this appointment one year later to become professor of pathology in the University of Glasgow, an appointment which he has continued to hold since that time. He is a member of the Medical Research Council.

An Interesting Bibliographical Gift.

On relinquishing office as president of the Royal Faculty of Physicians and Surgeons of Glasgow at the annual meeting, on November 4th, Mr. G. H. Edington presented to the Faculty an interesting memorial of its founder, Peter Lowe. The gift took the form of the first edition of Lowe's *Whole Course of Chirurgerie*, published by Thomas Purfoot, London, in 1597. The library already contained copies of the second, third, and fourth editions of Lowe's *Chirurgerie*, and, with this presentation, it now possesses a complete set of all the works and editions of Peter Lowe. Copies of the first edition of this book are extremely rare. One is known to be in the Radcliffe Library, Oxford; another is in London in the library of the Royal Society of Medicine, and a third copy is in the possession of the Royal College of Physicians of Edinburgh. The destination of a fourth copy, sold in London in October, 1924, for £120, is unknown. The copy presented to the Faculty library in Glasgow by Mr. Edington is slightly imperfect, lacking some few of the end pages. Otherwise it is in very good condition. The Faculty accepted the interesting gift with enthusiasm, and cordially thanked the donor.

Maternity Services and Child Welfare Schemes.

Reference was made in the *Journal* of October 5th (p. 643) to a circular issued by the Department of Health for Scotland in regard to duties under the Local Government Act of this year, and a series of circulars to be issued by the Department was mentioned. A circular (No. 26) dealing with maternity service and child welfare schemes has now been issued. This points out that, under the provisions of the Act of 1929, the local authority for maternity service and child welfare from May 16th, 1930, will be the county council, including small burghs within its area and the town council in large burghs. The schemes at present in operation within small burghs and county districts will therefore cease to operate from that date, and the work will be merged under the county council. Local authorities may make such arrangements as they think fit for attending to the health of expectant mothers, nursing mothers, and children under 5 years of age, subject to the sanction of the Department. County councils will thus require to submit schemes for sanction, although the large burghs will probably continue the schemes already in existence. It is also pointed out that the infantile mortality rate in Scotland is decreasing, but is still materially higher than the rate for England, and that puerperal mortality, which accounts for more than 6 deaths per 1,000 births, has shown no sign of a definite decrease. In both cases the Department believes much of the mortality, and indeed much of the maternal and infantile morbidity, to be preventable. A complete and efficient ante-natal service, it is held, would save much prolonged suffering and disability, including blindness from ophthalmia, deformity from poliomyelitis, rickets, or tuberculosis, and crippling heart conditions. The facilities outlined for mothers include instruction in general hygiene and maternity; the affording of medical assistance for illness connected with pregnancy, and of residential homes for necessitous women; provision of a midwife, doctor, or hospital treatment when necessary, and of home helps during the period of confinement; and the supply of food in necessitous cases. The arrangements in respect of children include the instruction of parents in the hygiene of childhood; home visitation; preventive clinics at centres; provision of hospital and convalescent accommodation, as well as play-centres, crèches, and places where healthy children can be received during the mother's absence or ill health; and the supply of food, including milk, in necessitous cases.

Welfare of the Mother.

Ante-natal clinics are required for women whose doctors are unable to keep them under supervision, and for women referred by doctors or midwives for consultation. The clinics will generally be provided at maternity hospitals, and the instruction of mothers will be undertaken here by health visitors, or, if need be, by the medical officers. The medical officer of the clinic should be an experienced obstetrician, and he will be assisted by a health visitor or nurse. There should be an arrangement for the provision of hospital beds for any women found to require in-patient treatment. Mention is made of the increasing desire on the part of expectant mothers to have their confinement in a maternity home; in other cases, arrangements should be made by local authorities to enable women in necessitous circumstances to obtain the services of a midwife, and in places where the standard of practice is found to be low it may be necessary to introduce well-trained midwives into the locality, with, if necessary, a guarantee of a minimum income. It is recommended that a rota of doctors should be formed for rendering assistance to midwives in cases of emergency. In the provision of maternity hospitals and homes sufficient accommodation should be secured not only for abnormal confinements, but for patients requiring ante-natal treatment, and for patients whose home conditions are such that they cannot be safely confined there. Definite arrangements must also be made for cases of puerperal fever requiring hospital treatment. The need for the establishment of homes attached to maternity hospitals is also considered.

Child Health.

The object of the Notification of Births Act is to enable the medical officer of health to take any steps desirable for supervising the health of the infant, and for the instruction of the mother in its management. An adequate staff of health visitors will be necessary to undertake systematic visitation of these infants; every child not medically attended at birth should be visited after birth by a medical practitioner, while the health visitor should visit weekly for the first month, and thereafter at longer intervals, until the child comes under periodic examination on entering school. The pre-school child should be encouraged to attend regularly at a health centre, in addition to this home visitation, and every effort should be made to secure medical examination at least twice a year. The primary function of centres is intended to be supervision, and mothers and children in need of treatment other than for minor ailments should be referred to the family medical practitioner or the treatment centre. It is suggested that local authorities might render the present school clinics available also for mothers and for children under the age of 5. The accommodation and equipment desirable at such a centre are indicated. Treatment centres are to be established for ophthalmic and dental work, for throat, ear, and skin diseases, and for sunlight treatment; if possible, these special treatment centres should be associated with general or children's hospitals, where facilities exist for supplying in-patient treatment which may be necessary.

Edinburgh Conference on Tuberculous Milk.

A conference, summoned by the Government, was held on November 8th at the Department of Health Office, Princes Street, Edinburgh, at which Mr. Tom Johnston, M.P., Parliamentary Under Secretary of State for Scotland, presided. It was attended by representatives of medical research bodies, public health officers, and officers of the various Government departments in Scotland, and the object of the conference was to co-ordinate research work in relation to public health. It was pointed out that something like 10 per cent. of the milk coming into large cities in Scotland was infected with bovine tuberculosis, and the discussion centred on the question of bovine tuberculosis and its effect upon public health. Attention was drawn to the heavy annual charge upon public health funds made by sanatorium treatment and other expenses connected with those suffering from the manifestations of this disease. At the conclusion of the conference a liaison committee was appointed to act between research organizations and local authorities in Scotland. The committee consisted of Dr. J. Parlane Kinloch, chief medical officer, Department of Health for Scotland, Sir Walter M. Fletcher, secretary of the Medical Research Council, Dr. J. B. Orr, director of the Rowett Research Institute, Aberdeen, Sir Robert Greig, Professor E. P. Cathcart, Professor F. A. E. Crew, Professor T. J. Mackie, and Mr. John Jeffrey, secretary of the Department of Health for Scotland. Dr. Kinloch was appointed chairman of the committee.

Anthropology and Medicine.

At a recent meeting of the Aberdeen Medico-Chirurgical Society Professor Alexander Low delivered his presidential address entitled "Anthropology and medicine." He pointed out that while undoubtedly hygiene and better nutrition had been all-important factors in making for better health, there was another factor which had to be taken into account—namely, racial inheritance. The influence of heredity in perpetuating the familial diseases had been fully recognized, but he suggested that in the study of not a few medical problems help could be derived from a knowledge of the process of race development and its social bearings. In Scotland much less displacement of population by invasion had taken place than was commonly supposed, and racial types could be traced in varying proportions in different parts of the modern population; thus the study of racial strain was a matter of practical importance. As regards the racial origins of the Scottish people there was a primitive substratum from Palaeolithic days along with representatives from the Nordic, Mediterranean, and Alpine races. The tall, fair, long-headed Nordic man was more suited to rural than town conditions, and there was evidence (E. G. Bowen) that in towns he was more liable to diseases—rather prone to tuberculosis, when depressed into industrial poverty. The broad-headed Alpine was an element that entered largely into the make-up of the people in the North-East of Scotland, and was characterized by patience, thrift, and caution. The short, dark, long-headed Mediterranean type was found in the poorer quarters of the large cities, for example in Glasgow, where they seemed to resist disease caused by overcrowding. In Glasgow the infant mortality had shown a uniform fall, and it was argued that the large proportion of immigrant Irish and Jews had added vigour to the native stock in withstanding the adverse conditions of city life. Some seven years ago, with the co-operation of Professor R. G. McKerron at the Aberdeen Maternity Hospital, and Dr. James A. Stephen of the Child Welfare Centre, Professor Low had begun to follow up growth in infants, and from that had been led to study how far and in what way, if any, racial type affected development. Knowledge of the physical characteristics of the pre-school child had been previously based on single measurements of groups of infants, and there was thus no way of estimating the degree of variation in the same individual child from year to year. This method of following up growth in individual infants was slow and laborious, and though for the past seven years many infants had been under observation the work was still far from complete. Some 1,000 infants had been examined at birth and measurements recorded, with so far as possible yearly re-examinations. In the Aberdeen infants the average birth weight of the male infant was 3,458 grams (7.625 lb.), and of the female 3,444 grams (7.59 lb.). It was of interest to note that there was little difference between the average weights of the two sexes, and infants born in Aberdeen were from six to eight ounces heavier at birth than those born in other towns in Great Britain. The average birth length of males was 49.2 cm. (19.3 in.) and of females 48.7 cm. (19.18 in.), about one inch less than the usually accepted average birth length. The average weight of the same group of infants at 12 months was 9,240 grams (20.37 lb.) for males and 8,306 grams (18.312 lb.) for females, and the average length at 12 months for males was 72.0 cm. (28.375 in.) and for females 70.1 cm. (27.625 in.). The effect of different rates of growth on development and its racial meaning were discussed. Study of the growth of the pre-school child was a matter of urgent importance, and to be of real value the individual child had to be observed year by year and the associated groups of characters recorded. Professor Low concluded by saying that much more anthropological research was needed, and that race study would develop great practical value for education and preventive medicine.

Professorship of Botany at St. Andrews.

Professor Robert A. Robertson, M.A., was, on November 8th, installed in the recently founded chair of botany at St. Andrews University, with charge of the departments of botany in the United College, St. Andrews, and in University College, Dundee. Professor Robertson was appointed lecturer in botany at St. Andrews in 1891, being one of the first lecturers appointed in the development of a school of medicine at St. Andrews and Dundee. He was made reader in botany in 1915. The ceremony took place in the University Library, and was performed by Principal Sir James Irvine, who said that the appointment would give great satisfaction both to Professor Robertson's colleagues and students, in view of the long services which he had rendered to the University.

England and Wales.

Tuberculosis in Lancashire.

In his annual report for 1928 Sir George Newman called attention to the particularly striking decline in the incidence of tuberculosis and in the corresponding mortality rate in Lancashire. The death rate due to pulmonary tuberculosis in that county in 1928 was 0.58 per 1,000 of the population, and, as in previous years, compared favourably with the corresponding rate (0.75) for England and Wales. The death rate in 1928 due to non-pulmonary tuberculosis in Lancashire (0.15 per 1,000) was, like the pulmonary rate, the lowest ever recorded in the county, and, in the fifteenth annual report on the work of the tuberculosis department, Dr. G. Lissant Cox, central tuberculosis officer for Lancashire, comments on these facts. The considerable advances made in sanitation in homes and workshops are, he agrees, undoubtedly contributory factors, while improvements in personal hygiene and the advance of education played a definite part. Nevertheless, the tuberculosis death rate has declined more rapidly in recent years than the death rates from all other causes. Dr. Lissant Cox has little doubt that this should be attributed in part to the better supervision of the patients' home conditions which has been effected, and the isolation in hospitals of infective cases when the home conditions are bad. The long-lasting industrial depression in Lancashire is, he considers, militating seriously against greater progress, and, indeed, temporary setbacks are to be expected if better conditions of employment do not develop soon. As regards the incidence of tuberculosis, the number of new cases of tuberculosis notified in 1928 was the lowest on record; Dr. Cox finds that both the pulmonary and the non-pulmonary forms are more prevalent among males than females. As in recent years pulmonary tuberculosis proved to be most fatal to females between the ages of 15 and 25; the figures for males in 1928 showed a remarkable evenness of mortality in the four age groups 15 to 25, 25 to 35,

35 to 45, and 45 to 55. Combining the death rates of both sexes the age group in which the heaviest mortality is now found is 15 to 25. This marks a considerable change in the last forty or fifty years, the mortality having definitely shifted in the direction of young adults, a change attributable to a distinct reduction of deaths of persons between the ages of 25 and 55, and not to any increase in the deaths among young adults. A considerable reduction has been effected in the past seventeen years in the number of deaths in the first five years of life, and to a smaller extent between the ages of 5 and 15. Recent researches undertaken in the county leave little doubt that an open pulmonary case may be the cause of non-pulmonary infection of a child, and, consequently, the reduction in the number of pulmonary cases, and their more rigid supervision, have helped to reduce the number of children with non-pulmonary disease.

The fate of young children who are members of tuberculous households has been the subject of an inquiry in Lancashire since 1925, and a report was issued last March, which was the subject of comment in our columns on May 18th (p. 918). It may here be recalled that the death rate from non-pulmonary tuberculosis of children exposed to risk in tuberculous households from adults with tubercle bacilli in the sputum was greatly in excess of the rate from the same cause in the geographical county of Lancaster, which served as a control in the investigation; it was nine times greater in the first twelve months of life, fourteen times greater in the age group 1 to 2 years, and nineteen times greater in the age group 2 to 5. Following the practice of previous years, new methods of treatment have been tried generally on patients in county sanatoriums and hospitals, under careful medical control. Dr. Lissant Cox, in his report, gives details of various preparations so investigated and the conclusions reached so far. The value of ultra-violet irradiation in non-pulmonary tuberculosis has been for several years recognized in Lancashire. He attributes much of the success thus attained to the fact that the tuberculosis officers themselves conduct the treatment, and that there is no dual control in this respect, as is the case in other places where less satisfactory results have been reported. Tuberculosis medical officers are given special facilities in Lancashire for specializing in light therapy, and it is calculated that over £1,200 was saved in the year by using this treatment in dispensaries as an alternative to sending the patients to hospitals. Light therapy has proved particularly useful in the case of patients suffering from tuberculosis of the skin and tuberculous adenitis, with abscess formation and skin involvement; it is not, however, recommended for pulmonary tuberculosis. Another prominent feature in the report is the improvement that has been effected in the last ten years as regards the notification of tuberculosis, and the belief is expressed that in Lancashire a much smaller proportion of cases escape notification than is the experience elsewhere. This results in diminution of sources of infection and contributes to the reduction of the number of new cases. Detailed reports are given of the various dispensary areas and residential institutions. Work began last August on the construction of new pavilions and other blocks for Wrightlington Hospital, Parbold. This new institution, when completed, will accommodate 60 adults and 146 children suffering from non-pulmonary tuberculosis, and 20 patients in whom both pulmonary and non-pulmonary forms occur together. As in previous years Dr. Lissant Cox's report is excellently illustrated. It constitutes a valuable record of an intensive campaign against tuberculosis, with the results that may be looked for when all the agencies concerned are closely co-ordinated.

West Bromwich and District General Hospital.

The medical committee of the West Bromwich and District General Hospital, in its annual report for the year ended June 30th, 1929, records with deep regret the loss the hospital has sustained through the death of Mr. Martin Young, who, as ophthalmic surgeon for over thirty-six years, had given devoted and faithful service. In his place two honorary ophthalmic surgeons have been appointed—Mr. Charles Rudd and Mr. E. B. Alabaster, both of Birmingham. Further new appointments have been those of Dr. W. R. A. Line of Handsworth and Dr. A. Frost of Wednesbury, as honorary anaesthetists. During the year under review 1,533 new in-patients—the largest number on record—were admitted to the wards, the increase over the previous year being 128. The general death rate was 4.3 per cent., 2.3 per cent. having died within forty-eight hours of admission. The number of new out-patients was 7,688, as compared with 8,060 last year, and in the casualty department 10,171 patients were treated, as against 9,919 in the previous year. The committee expresses the hope that the erection of a new out-patient department will be possible in the near future, the present building being out of date and unsuitable for dealing with the large number of patients who attend each day.

Belgium.

[From our Correspondent.]

A Monastic Medical Institution.

At the annual congress known as the Journées Médicales de Bruxelles, Dr. J. Tricot-Royer, a learned medical historian, gave an admirable account of the medical institution which was once housed in the Abbey of Orval. It is generally held, and by some very strongly, that this ancient abbey was once a famous home of science, in which the predominant place was taken by various branches of the art of healing. The lecturer gave details of the medical personnel so engaged, and made special reference to the presiding dignitaries: *le frère-médecin, l'infirmier, le chirurgien, le pharmacien,* and *les serviteurs des infirmes.* He enumerated the various functions of each of these offices, and mentioned that several might have been combined in a single person. The influence of Orval as an authoritative and beneficent scene of medical and philanthropic work permeated the whole territory which came within the abbey's sphere of influence. Among those ruins of the abbey building of the eighteenth century which were still standing there were to be seen valuable relics of the courts which the monks had set apart for medical purposes, including portions of buildings covering an area of 40 by 240 feet. A description was given of the solarium at the bottom of the garden, where the monks used to go for "sun treatment"; the old botanic garden was being restocked by restoring to it certain plants found growing in the valley, to which they had been gradually introduced by the *frères botanistes* throughout the ages. At the conclusion of his lecture, Dr. Tricot-Royer uttered an eloquent appeal for the protection of the sole considerable vestige of the ancient medical institution of Orval, the magnificent eighteenth century pharmacy, which was in danger of destruction.

Infantile Paralysis.

A severe epidemic of infantile paralysis has raged in Belgium this year, rising to its height in the neighbourhood of Antwerp. The affection was of the spinal variety, but, as a rule, the cases were atypical. After three or four days of slight pyrexia the children developed mono- or hemi-plegic paralysis, with a syndrome of meningeal contracture, often spasmodic, and a hyperaesthesia, which was very marked in the affected limbs; the general condition was but slightly affected. The disease increased by spurts, after intervals of quiescence lasting a day or two, during which the functional restoration was so marked as to justify parents and medical attendants entertaining hopes of recovery. Examination of the spinal fluid revealed a marked increase in albumin, and a lymphocytic cellular count ranging between 6 and 80 per c.mm. The colloidal reactions were those characteristic of meningeal affections; the condition could only be regarded as a meningeal syndrome. Some cases presented the typical appearance of a flaccid monoplegia with rapid atrophy. Three cases ended fatally, the poliomyelitis passing into a subacute Landry syndrome. One of these cases was exhaustively investigated, and a complete report of the anatomical and

pathological conditions will be published later; the process appeared to be an acute anterior and posterior poliomyelitis. Dr. Bogaert called the attention of the Society of Neurology to the possibility and importance of making a diagnosis in the pre-paralytic stage of the affection, and to the therapeutic value of associating Netter's method of treatment—*the injection* of blood from a convalescent patient—with Pettit's serotherapy. He suggested that, during an epidemic, all children showing signs of a febrile digestive syndrome with meningeal implication or pain and a lymphocytic reaction of the spinal fluid should receive intramuscular injections. No form of treatment is of much benefit in the stage of paralysis, except in patients who are beginning to recover, or in return cases. The onset of the affection gives no help in estimating its gravity. In a single family one child, who presented an atypical condition, recovered spontaneously; another suffered from severe paralysis, with rapid atrophy.

Belgian Centenary Scholarships.

On the proposal of the scientific and literary section of the Commission for celebrating the centenary of the achievement of Belgian independence, and in spite of the opposition of two medical men (Professor Duesberg, Chancellor of the University of Liège, and Dr. Beckers), the Minister of Science and Arts has submitted for the King's approval a proposal legalizing the holding of a competition for fourteen "jubilee travelling scholarships," each of the value of 14,000 francs. The competition, which is being instituted in order to permit certain students at the higher education colleges to take part in the centenary celebrations next year, comprises the presentation of a thesis, three essays, and a public disputation. The thesis, which may be in manuscript or print, must deal with a topic directly or indirectly relating to Belgium or the Belgian Congo, whatever science is concerned. Three essays must also be submitted outside the subject of the thesis, but relating to the group of sciences from which the topic of the thesis was selected. These jubilee scholarships do not replace the annual Government scholarships, which will be offered for competition as usual. The financial provision entailed will be met from the funds at the disposal of the scientific and literary section of the National Centenary Commission.

The New Hospital St. Pierre.

The Queen of the Belgians recently laid the foundation stone of the New Hospital St. Pierre, in Brussels. This institution owes its existence to the initiative of Drs. Heger and Depage, and to assistance rendered by the Rockefeller Foundation. It is being erected at the side of the new Faculty of Medicine, and will attract the attention of foreign nations as a central institute of medical science.

Correspondence.

GENERAL MEDICAL COUNCIL ELECTION.

The "Medical Register."

Sir,—Voting papers in connexion with the election of Direct Representatives are being issued to-morrow (Thursday, November 14th) to all practitioners having registered addresses in England and Wales. Any such practitioner who has not received a voting paper, whether he wishes to vote in the election *or not*, should immediately communicate with the office in order to ascertain that his address is correctly entered in the *Medical Register*.—I am, etc.,

44, Hallam Street, Portland Place, W.1, Nov. 13th. NORMAN C. KING, Registrar, General Medical Council.

Election of Representative for Scotland.

Sir,—Will you grant me the courtesy of your columns to convey my thanks to the registered medical practitioners of Scotland for the renewed expression of their confidence. I shall do my best to deserve it.—I am, etc.,

Edinburgh, Nov. 11th. NORMAN WALKER.

"ACTIVATED" FLUORESCEIN IN THE TREATMENT OF CANCER.

Sir,—On my return from a visit to South Africa, extending over several months, I found a letter from Dr. Webster commenting on the fact that no reply had been made to his letter, published in the *British Medical Journal* of August 24th last (p. 367), in which he criticized the paper on "activated" fluorescein in the treatment of cancer, which had appeared in the *Journal* a fortnight previously. On inquiry, I find that my colleagues had decided to leave over the question of a reply until my return. I regret the delay, and now, though somewhat belatedly, proceed, so far as possible, to repair the omission.

In the first place, needless to state, we do not put forward, as Dr. Webster infers, any claim to a new "cure for cancer." We contend, however, that, in certain instances, at any rate, more favourable results can be obtained from the use of "activated" fluorescein than when *x* rays alone are employed. Concerning Dr. Webster's contention that the results of Dr. Mottram's experiments *in vitro* with sarcoma tissue, to which we referred, "cannot be carried over to tumours in the patient with rapidly changing body fluids," it may interest him to learn that had he attended the demonstration we gave in connexion with the recent International Conference on Cancer in London he would have seen there a patient in whom, as the result of treatment by means of "activated" fluorescein, a deeply ulcerated sarcoma of the foot had entirely healed up.

The tentative explanation of what Dr. Webster terms the "new ray" did not originate with my colleagues or myself, but with Professor Lindemann, F.R.S., of Oxford, who suggested to us that fluorescein, on activation, might give off secondary rays, probably in the region of the 500 band, the behaviour of which would differ from that of the ordinary beta or gamma rays. Apparently, however, no method of definitely settling the physical problem involved is at present available, but we are hopeful that investigation of the whole subject may shortly be undertaken.

Dr. Webster offers "two explanations alternative to that adopted" in connexion with "the first case treated." Had he, however, examined the photographs (referred to in our paper) which were published in the *Journal of Public Health* about a year ago he would, I think, have realized that neither of his alternative explanations was tenable. Again, Dr. Webster adversely criticizes the *x*-ray dosage as "very large," "full erythema doses were given." As to this point, Dr. Gouldesbrough asks me to state that the dosage employed was certainly not large, since, with one exception—a patient suffering from breast cancer, complicated with diabetes, who subsequently did well—none of the cases treated showed any sign of erythema, even after long-continued treatment. We hope before long to have the opportunity of publishing further details in connexion with the work, including brief clinical notes of all cases known to us which, for the time at any rate, may fairly be classified as "apparently recovered."

In conclusion, may I suggest that when Dr. Webster has himself tried out the work from the clinical side we shall welcome such further criticism as he may feel disposed to offer.—I am, etc.,

London, Nov. 11th. S. MONCKTON COPEMAN.

THE PATHOGENESIS AND TREATMENT OF ASTHMA.

Sir,—As time did not permit of my taking part in the discussion on asthma in Manchester, I trust you will permit me to make a few remarks in a letter. The discussion did not bring out any new point, and no discussion is likely to do so as long as asthma is regarded as a disease. The same old fallacies regarding the causation of the condition were reiterated and the poor old vagus was dragged once more to the footlights, although no new reason was given for its reappearance.

There are no biochemical changes in the blood peculiar to asthma, and the abnormalities detected are the same as those to be found in the other manifestations of disease

Asthma, like many other symptoms of disease, is occasioned by the precipitation of enlarged and agglutinated (hydrated) protein particles in the perivascular lymphatic vessels and capillaries. Why the lungs are picked out to produce asthma, the brain epilepsy, migraine, etc., and the skin urticaria, angio-neurotic oedema, etc., need not be discussed for the moment. Whenever hydration of the protein particles in the plasma becomes pathological the percentage of one or more of the adsorbed constituents is decreased (the rationale of hypoglycaemia), the blood pressures fall, and signs and symptoms are produced which go by the name of "vagotonic," although stimulation of the vagus may play no part in their production. These are the characteristics of shock, of which asthma is merely a form. When the hydration in the lungs is very marked the bronchioles are not constricted, although the alveoli are collapsed and the patient has pulmonary collapse or atelectasis. When the hydration undergoes the cyclical change of dehydration bronchitis and broncho-pneumonia are apt to result, and in these inflammatory conditions the bronchioles may undergo a greater degree of constriction than occurs in asthma. Therefore, constriction of the bronchioles is not the cause of asthma. The primary cause is the local precipitation of hydrated protein particles, and the absence of red blood corpuscles requiring oxygenation, as a sequence. There are no hard-and-fast lines of demarcation between atelectasis, asthma, and bronchitis, and no special type of dyspnoea accompanies them. In other words, expiratory and inspiratory dyspnoea are neither to be clearly differentiated nor to be regarded as characteristic of any one clinical condition. Fatigue aids asthma because it augments hydration; it has no action upon the suprarenal glands. The reason why allergic tests fail is because they merely draw attention to precipitants and blind the observer's eye to what occasioned the hydration in the first instance.

Treatment, to be effective, must aim at removing the initial cause of the hydration, at correcting the mal-co-ordination which all asthmatics present, and at bringing about dispersion of the hydrated protein particles. The first draws attention to the familial chronic intestinal intoxication, the second to the re-educationary methods practised by Mr. F. M. Alexander, and the third to the use of drugs. The choice of drug depends upon the type of asthma. For asthma in children, and when an attack in adults is caught at its inception, S.U.P. 36 is the best remedy. In prolonged attacks S.U.P. 468, parathormone, calcium and strontium aspartate, etc., are useful. In chronic cases acetylcholine may be required or more often iodine, thyroid, and contramine. Glucose is useful in all forms of shock, *merely because it breaks up the* enlarged protein particles, but it is not needed in asthma, and tends to increase the incidence of post-inflammatory troubles. Adrenaline behaves in much the same way as glucose; it has no sympathomimetic action, and its continued use may actually cause asthma, because all dehydrators occasion hydration in time. Atropine tends to aggravate asthma because of the initial hydrator effect of the vehicle, and, needless to say, *it does not* paralyse the vagus. Fear causes dehydration of the protein particles; it does not stimulate the suprarenal glands to hypersecretion, and Cannon's work is based on indirect evidence only. Excessive fear, which is the same as shock, causes hydration, and if Cannon's view is correct shock should occasion the maximum output of adrenaline, but the drug is used as an antidote to the condition. Prevent and get rid of familial chronic intestinal intoxication and there would be no asthma and no need for the establishment of futile committees.—I am, etc.,

London, W.1, Nov. 8th. J. E. R. McDONAGH.

SIR,—The views expressed in your last issue by Dr. Hurst on the question of asthma are so opposed to my experience in treating that complaint that I should not like them to pass unchallenged, or to appear as the last word on the subject.

Dr. Hurst has always been extremely antagonistic to the skin reactions, and has "come to the conclusion that they are of no practical value." He admits that there is such a thing as sensitization, or hypersensitization, as for some reason he calls it. For he says in another part of the article—

"It is none the less of the greatest importance to give every asthmatic an exhaustive cross-examination with the object of discovering whether some or all of his attacks are due to his being hypersensitive to the proteins of one or more articles of food, an animal emanation, a pollen, house-dust, orris-root face powder, or the toxins of some organism."

The mantle of Sherlock Holmes may have fallen on Dr. Hurst, but for my own part I should consider it utter waste of time to exhaust either the patient or myself in trying to distinguish between the effects of a feather bed, a horse-hair mattress, and the family cat by dint of cross-examination, when the dermal tests will so easily impute to each their share in the causation of the patient's asthma. Just as every patient suffering from seasonal hay fever gives a reaction to pollen, so, without exception, those having asthma from other proteins will respond to those proteins if properly applied to the skin.

During the past week I have seen my 2,000th case of asthma; all of these, but for some half-dozen cases, have been tested with the proteins, with the result that scores of these patients have been freed from their asthmatical symptoms by the dermal reactions alone. Any resurrection of the word "diathesis," with an attempt to find a single biochemical shortcoming for all cases of asthma, seems to me to be doomed to failure because the many clear-cut types of asthma which I recognize are so extraordinarily different from one another.

It astonishes me that Dr. Hurst should mention nasal polypi without, in the same breath, referring to the aspirin sensitive type, a very clearly defined type recognized by Dr. Alexander Francis, and described by myself many years ago. Lastly, I strongly object to the practice of *teaching patients to fly to the hypodermic syringe* and adrenaline as a routine measure. This should only be necessary in a very few cases. On the other hand, no mention is made of such well-recognized procedures as the injection of peptone and many other measures designed to remove the cause of the attacks rather than to deal with the paroxysm only after it has started.—I am, etc.

London, W., Nov. 11th. FRANK COKE.

SIR,—In the most instructive leading article on the asthma problem in last week's *Journal* (p. 865) attention is drawn to the experimental observations of Brodie and Dixon published in 1902. In the record of these observations it was stated that contraction of the bronchial muscle could be brought about by irritation of the nasal mucous membrane, *especially on the upper and posterior part of the septum.* In the light of this irresistible evidence they offer as to the preponderating effect of intranasal irritation in exciting the contraction of the bronchial muscle, I am surprised that no reference is made, as the natural corollary, to the importance of careful intranasal examination and, when required, intranasal treatment. May I refer your readers to the article on "The nasal factor" in the treatment of asthma" in the July number of the *Practitioner* (p. 18) mentioned in your leader.—I am, etc.,

London, Nov. 11th. JAMES DUNDAS-GRANT.

GLUCOSE IN THE TREATMENT OF ASTHMA.

SIR,—I regret that in the published version of my opening address on asthma at the meeting of the British Medical Association, which appeared in your last issue, there is no mention of the name of the physician who is responsible for one of the most important recent advances in treatment—the administration of glucose. In the children's department at Guy's Hospital Dr. H. C. Cameron has for some years constantly taught that attacks of asthma in the predisposed are brought on by a condition of glycopenia, and that, while in other respects asthma may be difficult to treat, the glycopenia can be satisfactorily overcome by the administration of glucose, with the result that the asthma often disappears. It should be clearly understood that the entire credit for this important discovery is due to Dr. Cameron, and that the

recent research done in this connexion by Dr. Oriel at the special asthma clinic at Guy's Hospital is nothing more than a continuation of the work which Dr. Cameron has so well initiated.—I am, etc.,

Berkshire, Nov. 11th. ARTHUR F. HURST.

THE CANCER PROBLEM.

SIR,—The question whether cancer is due to a micro-organism still awaits an answer. Experimental proof so far has not passed the necessary tests. Clinical evidence is not in favour of it. If cancer were due to a micro-organism it seems probable that surgeons would have become infected by it in the course of operations, as they have been so often by tubercle and syphilis, but such a thing is not known. No importance can be attached to the fact that a few cases have been reported in which cancer appears to have been transmitted by direct contact. Nearly all of them admit of other and simpler explanations, and, in any case, the number is so small that they may be regarded as coincidental outbreaks.

Cancer is not a uniform growth; its cells vary in appearance according to the structure from which they grow, for each organ has its own peculiar kind. Cancer, like other tumours, is the offspring of a process of asexual reproduction, a process which still plays a very large part in the animal kingdom, but which, so far as the higher forms of life are concerned, is obsolete, but not extinct, as the structure and development of many ovarian teratomata prove.

Cancer is caused by the persistent action of chemical and physical stimuli which interfere with the nutrition of the tissues to such an extent that their work and development are seriously impaired, and sometimes stopped altogether. When this occurs, the young embryonic cells, with all their primitive power of reproduction intact, unable to work or develop as they should, multiply and increase in number until they reach the limit where growth spreads beyond the individual and a new structure, which really belongs to another generation, comes into existence. This new structure, the presence of which is resented by the tissues around it as if it were a foreign body, is composed of cells like the parent cell in all respects. Each cell has a life of its own separate and distinct from that of its fellows and that of the parent organism, upon which it grows like a parasite, drawing from it all that it requires in the way of nourishment, and not doing anything for it in return, capable of invading all the structures around, and giving birth to growths like itself with the same powers and limitations. That is cancer.

X rays, unless proper precautions are taken, are a common cause of cancer. So are such chemical substances as soot, tar, and some mineral oils, especially if assisted by mechanical irritation, only they act much more slowly. Other chemical substances will produce the same effect on internal organs. Workers in aniline dyes, for example, are especially prone to cancer of the bladder. Mechanical irritation alone will not cause it, but assists materially by the injury it inflicts on the tissues, and the changes that necessarily follow.

Cancer is more common in old age, partly because of the cumulative effect of repeated stimuli, partly because, as in organs that are past their prime, the vital activity of the tissues is lower, and less able to resist. Cancer of the breast rarely occurs while the organ is in full functional activity, but later, when its work is done, and involution is setting in.

The transition from the effects of simple irritation to the production of cancer can be traced step by step in cases in which the skin has been unduly exposed to the action of *x* rays. The superficial cells are killed and thrown off. Their development was complete and their reproductive power consequently exhausted. The cells immediately beneath, whose function it is to grow up and replace them, are not so much affected, but their development is checked. The skin becomes harsh and dry and its surface red and glazed; it looks as if it were shrunken on to the parts beneath. Later, if the cause continues at work, the young cells begin to collect in numbers, but some degree of development is still possible. Warts and papillomata, and, when the deeper layers of the skin are involved, small fibrous tumours, make their appearance. Later still, development stops altogether and the young cells continue to multiply unchecked until, at some point, growth extends beyond the individual and cancer breaks out. It is always strictly local at the beginning.

It is noteworthy that none of these agents, not even the *x* rays, are the instant cause of cancer. They act by inducing a permanent and progressive change in the nutrition of the tissues so that they can neither work nor develop as they should, and this persistent change is the cause. Cancer has been known to develop years after the external cause has ceased to act and has even been forgotten. It is true that cases that can be accounted for in this way form but a very small proportion of the total, but they are definite, and it is impossible not to associate cause and effect.

The problem is really a double one. One is to ascertain under what conditions simple growth can suddenly be transformed into growth beyond the individual, a subject which can best be studied in the lower forms of animal life in which asexual reproduction is, if not the rule, at least exceedingly common. The other is to find out whether there are not chemical substances absorbed from the alimentary canal, or perhaps formed in the tissues themselves, which in the course of time are capable of checking the functional activity of the young cells, arresting their development, and so releasing their reproductive energy from all control. Arsenic is a case in point. I am convinced from cases I have seen that persons habitually taking arsenic are especially liable to epithelioma of the skin, and there is reason to believe that some of the products of chronic constipation are not above suspicion.—I am, etc.,

London, W., Nov. 5th.

QUININE AND BLACKWATER FEVER.

SIR,—More than five-and-twenty years ago, on my return from Africa, after a residence of three years, during which I had three attacks of blackwater fever, Sir Patrick Manson asked me what I thought was the cause. I unhesitatingly replied that in my opinion the malignant tertian parasite was the root cause *plus* some unknown factor, and that this unknown factor was in some way connected with the ingestion of quinine, as I had never seen a case which had not immediately followed a dose of quinine (irrespective of the dose taken). Now of all the forms of malarial fever malignant tertian is the most insidious, and it is not uncommon to find the parasite in the blood of those who definitely assert that they never have had an attack of malarial fever in their lives! Hence it is often the case that these victims of the disease either never take quinine at all, thinking that they are immune to malaria, or only take it spasmodically in small doses, imagining that this will act as a preventive.

When I contracted my first attack in 1901, after a year's residence on the shores of the Victoria Nyanza, I never had been a single day on the sick list. An epidemic of small-pox raged through my province, and I had to work hard to cope with the hundreds of cases. While thus engaged I was bowled over with an attack of fever. Thinking that I had at last got a malarial attack, I dosed myself with quinine in repeated doses, and on the following day woke to find that my urine was "black." After twenty-four hours of this I felt a papular rash on my forehead, and at once knew that I had small-pox. The blackwater disappeared completely in three days, and the small-pox ran its course. As soon as I found that I had small-pox I knocked off the quinine.

Throughout my service of sixteen years I had altogether five attacks of blackwater fever, and whenever the means were available I found malignant tertian parasites in my blood, although in the intervals between my attacks I was never aware of malarial fever. Incidentally I may say that, although I was called upon to treat many cases, I only had one death—my first case. Here treatment had no chance, as the patient died a few hours after my

arrival; he had been obliged to travel daily until, in a desperate condition, he reached a Government station.

In treating these cases I invariably assumed, if I did not already know for certain, that the malignant tertian parasite was present in the blood, and gave quinine, at the same time making sure that the liver was acting. In point of fact, I usually started on the liver first, since there is small hope of overcoming any malarial attack when this organ is not acting properly.

I must confess that after all these years I am no nearer the discovery of the actual cause of the disease. Malignant tertian, in my opinion, is certainly the predisposing cause, but what is that other factor? In malarial countries everyone flies to the quinine bottle whenever a feverish attack seems imminent, so, naturally, when one is called to a case of blackwater fever, quinine (usually in a small dose) has already been taken; without stronger evidence it would be dangerous to regard it as the exciting cause.

In our present ignorance we like to take protection under the shield of "idiosyncrasy"; if I remember rightly, I think this was the very word I used to Sir Patrick Manson when we discussed the disease in 1903. For a long time I was under the impression that this special haemolytic behaviour of the malarial parasite was due to a particular virulent strain of the malignant tertian parasite, but of late years I have inclined to the belief that the weak point will be found in the victim's own particular red blood cells, which are more easily broken down by the toxins of the parasite. Whether this (? temporary) excessive fragility of the red corpuscles is due to some endocrine imbalance remains to be discovered, and possibly rests, as Dr. Booth suggests, with the biochemist.

A curious point about the victims of the disease in all the cases which I came across was that they were all particularly active individuals—mentally, physically, or both. Possibly this explains their neglect of themselves until they were actually bowled over.—I am, etc.,

London, W.1, Nov. 9th. R. E. Drake-Brockman, M.D.

THE BEGINNING OF THYROID THERAPY.

Sir,—Last month a woman patient of mine died, aged 87. I write about her because, if not the first, she was one of the first persons to be treated in Leeds for myxoedema after the discovery by Dr. George Murray that thyroid extract relieved this disease. She was under my care at the time the announcement was made at Newcastle in 1893 at the Annual Meeting of the British Medical Association. The diagnosis had been confirmed by Dr. Barrs of Leeds. The treatment was carried out by means of intramuscular injections of thyroid extract, which was received by post, in a fresh state, from Brady and Martin of Newcastle every three or four days, and was used immediately. The injections were given in the interscapular area. The last injection the patient received caused a very large abscess; improvement took place rapidly, but I fail to remember how many injections were given. The curious feature of the case is the complete cure which was effected: there was never any recurrence of symptoms; I have never seen this since. The patient enjoyed good health until recently, death resulting from asthenia due to old age.—I am, etc.,

Leeds, Nov. 4th Arthur Hawkyard, M.D.

NASAL DISCHARGE IN CHILDREN

Sir,—I have read with interest the papers on the above subject by Dr. Gilhespy and Dr. Douglas Guthrie (November 2nd, pp. 803 and 805), but in neither of them is there any mention of foreign bodies in the nasal cavities as a cause of nasal discharge in children.

Workers in the throat, nose, and ear departments of hospitals see from time to time children with persistent unilateral or even bilateral nasal discharge, the cause of which proves to be the presence of some foreign body—for example, a pea, a button, or a piece of string—which the child has pushed up its nostrils. Usually these bodies are to be found lying on the floor of the inferior meatus, and the discharge will persist as long as they remain there. Dr. Guthrie's mention of breathing exercises prompts me to add the following directions for carrying out such exercises; they appear on a printed form that is given to every parent whose child has had an operation at the Royal West Sussex Hospital for tonsils and adenoids.

Position 1.—Stand with the body and head erect, chin slightly drawn in, the chest expanded, eyes looking straight forward, knees well braced back, heels together, toes turned out, so that the feet together form about a right angle, the weight of the body on the fore part of the feet, with the lips tightly closed (the teeth not clenched, however) so that the breathing may be entirely through the nose, both in inspiration and expiration. Gradually bend body forward till hands touch the feet, at the same time emptying completely the chest.

Position 2.—Gradually rise from this position to position 1, filling up chest to fullest capacity, with hands well raised up and behind head.

Position 3.—Place the left forefinger on the left nostril so as to occlude it, bring the right arm up and out, fully extended to level of the shoulder, at the same time taking a deep breath through the right nostril till chest is fully expanded, then bring arm back to former position, emptying chest at the same time.

Position 4.—Repeat for opposite side.

General Directions.—(1) All exercises are to be done with as little clothing as possible. (2) Preferably out of doors. (3) At rate of about 12 to the minute. (4) Mouth always closed. (5) Twenty of each to begin with, two or three times a day, increased till fifty can be done with comfort. (6) These exercises should be persisted in for at least six months. (7) If there is snoring, or mouth is kept open at night, a chin strap should be worn.

—I am, etc.,

Arthur M. Barford,
Consulting Surgeon, Portsmouth Eye and Ear Hospital; Surgeon and Aural Surgeon, Royal West Sussex Hospital.

Chichester, Nov. 4th.

PSEUDO-TUBERCULOUS PERITONITIS.

Sir,—In the course of dispensary work we frequently have to examine children of school age who have been sent to us as definite or tentative cases of tuberculous peritonitis. There is a history of some loss of flesh, pain in the upper abdomen, fickle appetite, and irregular action of the bowels. Some tumidity of the abdomen is evident with varying degrees of tympanites; but no mass or fluid can be discovered. The superficial veins on the chest are too visible, and the heart's impulse more than usually pronounced, with generally definite abnormality of rhythm and sounds. A history of sore throat and discharge from the ears can generally be elicited and nail-biting is somewhat common. The D'Espine sign is often to be found, but the von Pirquet skin test is definitely negative; tubercle bacilli were not found in the faeces, and the subsequent history shows that a pathological heart lesion is more likely than the development of tuberculosis. Is this syndrome one of the vagaries of streptococcal infection?—I am, etc.,

Newport, Mon., Nov. 6th. J. L. Thomas.

RELIEF OF PAIN IN LABOUR.

Sir,—In his article on hyoscine amnesia in labour in the *Journal* of November 2nd (p. 801), Dr. D. R. Jennings states that this method was undertaken as "an outcome of the suggestion that the morphine used in the twilight sleep method was responsible for the asphyxia or oligopnoea in some of the newborn." This idea is an old one, but, I think, has no basis in fact where the morphine has been limited to the first injection. Dr. W. O. Greenwood, in an article on amnesic narcosis,[1] discusses this point at length. He remarks that if definite asphyxia was "really due to scopolamine-morphine it certainly indicates a gross overdosing just as does analgesia," and goes on to plead for the individualization of patients.

In 1926[2] I recorded 100 consecutive cases of twilight sleep; they were unselected, and morphine was given with the first dose only of hyoscine. The few cases of oligopnoea or asphyxia could be accounted for by difficult labours, and

[1] Fairbairn's *Practitioners' Encyclopaedia of Midwifery and Diseases of Women.*
[2] *Lancet*, 1926, vol. i, p. 338.

three years' subsequent experience confirms this; I agree with Dr. Jennings that the great majority of "babies at birth showed signs of active life rather more readily than in normal cases"—that is, cases without hyoscine; most of them cried lustily and spontaneously, but briefly, immediately they were born.

Dr. Jennings rather stresses the restlessness of some of his cases, and the need for mechanical restraint: I suggest that this is due to the standardization of doses; one cannot expect the same reactions to the same dose from a woman of "hefty type" and from a thin small woman, whatever the latter's temperament. I have found in some cases that 1/150 or even 1/100 grain of hyoscine every hour was necessary to maintain amnesia and quiet, while in others 1/300 or 1/450 grain every three or four hours has sufficed. I have seen very few where restlessness has been marked and troublesome, and a few whiffs of chloroform work wonders with these; naturally the morphine gets the credit in part for the quietness. I am sure also that, where it can be given beforehand, suggestion of the efficacy of the treatment is of great value in securing both mental and physical repose, especially in the nervous and frightened type of patient. I have found very few patients who could not have been treated in their own homes or elsewhere without any other help than the usual one nurse; this, of course, involves individualized dosage and practically continuous attendance, as does the administration of any anaesthetic. It would be a pity to add frequent extreme restlessness to the erroneous ideas of blue babies, inertia, haemorrhage, and mentally defective children that are current not only among the laity, but among doctors and nurses also. I am entirely in agreement with giving a last dose shortly before birth, as the subsequent sleep is an important factor in securing amnesia.

I would like to see the first paragraph of Dr. Jennings's *Results* on page 802 reproduced in red ink and large type, and distributed to all who practise midwifery, in the endeavour to awaken their interest in the relief of pain in labour, so often neglected. Dr. John S. Fairbairn[2] and Professor Louise McIlroy[3] are authorities who have recently stressed the importance of this. Where pain from any other cause exists the patient expects relief, and the doctor does his best to afford it; but the pain of labour is often disregarded not only by the doctor, but by nurses and relatives also. The attitude seems to be that pain is inseparable from childbirth, their mothers had to put up with it, and so must they; no allowance is made for the changed mental attitude to which Dr. Fairbairn alludes. Many doctors, too, fail to realize the dread and anxiety with which even healthy young women contemplate the end of their pregnancy, however brave they try to appear. During labour the average doctor does not see the full extent of their suffering; he drops in from time to time to see how things are going, and promises chloroform at the end. At these visits the patient summons all her self-control, and the doctor has no conception of the intervening terror and agony she endures. I have often been told by patients that they had asked for "twilight sleep," but the reply has been that they were not suitable subjects, or that it was too dangerous if they wanted a live baby; it has been obvious that the doctor was unacquainted with the technique, which was the real reason for the refusal. Dr. W. O. Greenwood[4] states that 7 per cent. of his births were due solely to the knowledge that scopolamine-morphine treatment was available—a strong argument when remedies are being sought for the low birth rate.

Thus, although I do not agree with a standardized method of dosage, as described by Dr. Jennings, and think the addition of morphine to the first dose has advantages, his report is welcome as tending to spread the doctrine of the relief of labour pains by a simple method which is applicable by those who can spare the time, and gives a good percentage of results. The difficulty in general practice is, of course, to suspend all other work for periods up to twenty hours or more; where expense is no object arrangements can be made in advance for the constant attendance of another doctor to give the injections and watch the case. There is the added gain of individualized, as opposed to standardized, treatment, and a higher percentage of good results.—I am, etc.,

ARSENICAL IONIZATION.

SIR,—I was very pleased to see in the *Journal* of August 17th (p. 297) the article on arsenical poisoning by Dr. Dalton, since I think it helps to solve a point on which I have heard doubt expressed—namely, the passage of arsenic through the tissues by electric propulsion.

In 1916 or 1917 we were experimenting with ionization for the cure of "Baghdad boil" (dermal Leishmaniasis), and had obtained fairly good results using a 2 per cent. solution of magnesium sulphate, and other salts in various strengths of solution. Some cases, especially nasal cases, were very resistant to this treatment; we therefore decided to try an arsenical salt, since it was believed that the favourable results obtained with methylene blue were due to its arsenical impurities. The only arsenical salt that we had in the hospital was sodium arsenite, so this was used in a 1 per cent. solution in place of the magnesium sulphate, the positive and negative electrodes being reversed. The reaction was so severe that we had to discontinue the use of this solution, both because of the pain and also for fear that the tip of the nose might slough. In the few other cases in which we tried it the reaction seemed to cause a complete cure.

I have always thought that the difference in severity of the reaction was due to the entry of the arsenite ion into the tissues instead of the magnesium ion; but I have heard doubts expressed on this point. It would be interesting to hear the views of Dr. Dalton or others on this matter.—I am, etc.,

Taupo, New Zealand, Sept. 29th. J. SCAIFE ARMSTRONG.

TREATMENT OF INFECTIONS WITH S.U.P. 36.

SIR,—Mr. E. Horace Richards (November 9th, p. 877) asks for further details of my series of cases of acute mastoiditis treated with S.U.P. 36. May I preface my reply with the following observations? First, I agree with him entirely about the folly of trusting blindly to any drug in this "treacherous and dangerous disease." I would like to point out, however, that I stressed this particularly in my original letter. In actual practice I make arrangements to perform a Schwartze operation without delay should any symptoms become worse after injection. Secondly, all these cases were seen within twenty-four hours of the acute onset of mastoid symptoms, probably before irreparable damage to the middle ear and mastoid cells had occurred, and certainly before intracranial complications had set in. Excluding cases where myringotomy might reasonably have cured the patient I have notes of the following:

Case.	Sex.	Age.	No of Injections Given.	Otorrhoea before Treatment.	Persistent Otorrhoea after Treatment.
A	M.	17	2	+	—
B	F.	22	2	—	—
C	M.	12	1	+	—
D	F.	14	2	+	+
E	M.	7	2	+	+
F	M.	17	2	+	—

I will describe the last case in detail as it is fairly typical of the others, with a subsequent note of any deviations from type.

Case F.—J. R., male, aged 17. Acute otitis media, purulent discharge from right ear. Acute pain and tenderness in right mastoid region on the fourth day with cessation of discharge. Seen at 9 p.m. (seven hours after onset of acute pain). Temperature 102°; ear pushed forward; marked swelling and oedema over mastoid process. S.U.P. 36, 0.01 gram given. Next day all pain

gone, temperature 99°; swelling and oedema still present but diminished. There was profuse discharge from the ear. Injection repeated. On the following day the temperature was normal, and the discharge less. All symptoms and discharge were absent on the fourth day. Two large septic tonsils were removed fourteen days later.

Cases D and E were similar, but otorrhoea was more chronic before injection, and persisted for several weeks subsequently. This cleared up after removal of tonsils and adenoids.

Case C was one of acute double mastoiditis with unilateral otorrhoea. After one dose of 0.005 gram all clinical signs rapidly resolved, leaving no traces of disease.

Case B is perhaps a doubtful case to include as there was no previous history of discharge, but the local signs over the mastoid were very definite indeed and an empyema was suspected.

Case A was similar to the above, but followed a chronic otitis media.

In conclusion, may I repeat a warning as to the limitations of S.U.P. 36? It is very unlikely to improve any chronic condition, whether of the ear or any other part of the body. Its specific action is best shown in early acute disease, of which acute mastoiditis happens to be an excellent example, particularly in children and young adults. It certainly does not possess any miraculous power of renovating tissues damaged beyond repair, but, as Mr. J. E. R. McDonagh (October 19th, p. 738) states, it acts by increasing the patient's resistance and neutralizing toxaemia.—I am, etc.,

Walmer, Nov. 11th. JAMES S. HALL.

Obituary.

NINIAN McINTIRE FALKINER, M.D., F.R.C.P.I.,

Late Medical Superintendent of Statistics for Ireland.

THE death took place in Dublin recently of Dr. Ninian McIntire Falkiner, F.R.C.P.I., of Terenure, co. Dublin. Dr. Falkiner, who was a nephew of the late Recorder of Dublin, Sir Frederick Falkiner, and an uncle of Dr. Ninian Falkiner of the Royal City of Dublin Hospital, was a graduate in arts and medicine of Dublin University, where he had a distinguished student career. In 1878 he became a moderator in experimental science, and was awarded a silver medal. He graduated M.B. in 1884, gaining first place, and in the following year took the degree of Bachelor in Surgery. In 1889 he obtained the diploma in State medicine after gaining first place at the examination. Later he proceeded to the degree of Doctor in Medicine, and in 1891 was elected a Fellow of the Royal College of Physicians in Ireland.

At the beginning of his professional career Dr. Falkiner was for many years a Poor Law medical officer in one of the Dublin dispensary districts. He was an active member of both the British and Irish Medical Associations; he had served as president of the Leinster Branch and was one of the most regular attendants at its meetings. For about twenty years he was medical superintendent of statistics in the office of the Irish Registrar-General in Dublin, and also held the position of secretary to the Statistical and Social Inquiry Society of Ireland. He had served at various times as examiner in chemistry for the Royal Colleges of Physicians and Surgeons in Ireland, and also as an examiner in vital statistics and public health law for Dublin University. A writer of much ability, some of his contributions were on the subjects of notification of pulmonary tuberculosis, analysis of rhinolith, dosage of arsenical compounds, registration of diseases, and statistics of cerebro-spinal fever. During the great war Dr. Falkiner served in England as a temporary captain in the Royal Army Medical Corps at the Lord Derby War Hospital, and was mentioned for his services.

THE LATE PROFESSOR TUFFIER.

DR. ARTHUR LYNCH (London, N.W.) writes: Apropos of the death of the great French surgeon, Tuffier, whose service I followed for a time at the Hôpital Beaujon, it may be of interest to record one or two of his sayings. I once asked him what was his greatest feat of surgery. He replied: "For the public I could mention certain spectacular operations, but to members of the profession I would say, suturing a resected ureter end to end." At another time he remarked: "The greatest glory of a surgeon is to make a fresh observation or a discovery, to publish it, and find it come back developed by the observations of others and referred to the whole body of acquired science."

A well-known and popular medical man passed away in Dublin, on October 25th, in the person of Dr. PETER MCKENNA of Carrickmacross, aged 64. Born in co. Down, he received his early education in St. Malachy's College, Belfast. His medical studies were taken in the schools of the Royal University and the Royal College of Surgeons, Dublin. Graduating M.B. and M.Ch. in 1888, he practised for two years at Clones, co. Monaghan, after which, on being appointed medical officer and medical officer of health of Donaghmoyne dispensary district, he removed to Carrickmacross, where he remained till his death. Owing to failing health, he resigned his appointments four years ago. He was deeply interested in medical politics, being a very useful member both of the Irish Medical Committee and of his county medical committee. Previous to the Treaty he was justice of the peace for the county, and the Free State Government elected him a peace commissioner. He leaves a widow and three sons and three daughters. His two older sons served through the great war, and on being demobilized graduated in medicine at Trinity College, Dublin, and are in practice in London.

DR. GEORGE ALEXANDER PIRIE, who died in Dundee on October 27th, was well known as a worker in radiology for many years before he retired. He was the son of a Dundee medical practitioner, and studied medicine in Edinburgh, where he graduated M.B., C.M. with first-class honours in 1886; he proceeded M.D. four years later. In the summer of 1887 he acted as resident in the Royal Infirmary of Edinburgh to Sir Thomas Grainger Stewart, and afterwards commenced practice in Dundee. He was one of the early pioneers in x-ray work, having taken up that branch of work in 1896, very shortly after Roentgen's discovery of the possibilities offered by the x rays for medical diagnosis; his work in this connexion at Dundee Royal Infirmary extended from 1896 till 1925. In the early days of radiology the injurious effects of exposure to the rays were unrecognized, and Dr. Pirie, like other radiologists, was accustomed to work with unprotected tubes; this led to serious injury, which necessitated the relinquishment of his duties in 1926. In April, 1926, he was presented by a group of citizens of Dundee with a cheque for £1,120 in recognition of his useful and self-sacrificing work, while the Carnegie Hero Trust also awarded him in the same month its bronze medal and an allowance of £200 per annum. In 1927 he received a Civil List pension of £75.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE Faculty Board of Medicine has appointed Sir Frederick G. Hopkins, Dr. Louis Cobbett, and Mr. Arthur Cooke to be members of the M.D. Degree Committee until September 30th, 1930; and Professor G. H. F. Nuttall, Dr. W. E. Dixon, Mr. D. Keilin, Dr. Frank Robinson, and Dr. A. J. Laird to be members of the D.P.H. Committee.

UNIVERSITY OF LONDON.

DR. H. YELLOWLEES has been recognized as a teacher of psychological medicine at St. Thomas's Hospital Medical School, and Dr. J. F. Taylor as a teacher of pathology at St. George's Hospital Medical School, for the session 1929-30.

A University Readership in Chemical Pathology, tenable at St. Bartholomew's Hospital, is to be instituted.

Grants of £50 have been made out of the Thomas Smythe Hughes Medical Research Fund for 1929-30 to (1) H. Avery for research on the localization and treatment of cerebral tumours produced experimentally with Jensen's yeast cultures and with neoplastic grafts, and (2) Mary F. L. Keene and Evelyn E. Hewer for the continuation of research on the development of the human foetus.

Mr. C. Max Page has been appointed senior examiner in surgery for the remainder of the year 1929, in succession to Professor C. A. Pannett, resigned; Mr. A. W. Ormond, Sir John H. Parsons, and the senior examiner in surgery have been appointed as examiners for the M.S. degree in ophthalmology in December, 1929.

Candidr[illegible] public health examina-
tion who [illegible] the same occasion, but,
owing to [illegible]om sitting for Part II,
are to rec[illegible]ls.

The London School of Medicine for Women has been affiliated to the University Union.

UNIVERSITY OF LIVERPOOL.

The William Mitchell Banks Memorial Lecture will be given by Professor C. Regaud, M.D., director of the Pasteur Laboratory, Radium Institute, Paris, in the surgical theatre of the Medical School of the University of Liverpool on Thursday, November 21st, [illegible]n the curative movements." [illegible]slides, is open

Dr. H. H. Gleave has been appointed senior lecturer in pathology.

UNIVERSITY OF ST. ANDREWS.

Sir Wilfred T. Grenfell, K.C.M.G., M.D., of Labrador, was installed Rector of St. Andrews University on November 6th, in succession to Dr. Fridtjof Nansen, G.C.V.O.[illegible]

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The annual meeting of Fellows and Members will be held at the College in Lincoln's Inn Fields on Thursday, November 21st, at 3 p.m., when a report from the Council will be presented. Fellows and Members can obtain copies of the report on application to the secretary, and can, if they so desire, have their names placed on the list of those to whom the report is sent annually. A copy of the agenda will be issued to any Fellow or Member who may apply for one.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A quarterly meeting of the Royal College of Physicians of Edinburgh was held on November 5th, with the President, Dr. Robert A. Fleming, in the chair.

Dr. William Thomson Munro was introduced and took his seat as a Fellow of the College.

Bursary in clinical medicine to W. V. Anderson, and the Wood Bursary to J. MacG. Drever.

Medical Notes in Parliament.

[From our Parliamentary Correspondent.]

The House of Commons spent three days this week in committee on the Widows', Orphans', and Old Age Contributory Pensions Bill. Private members' business occupied the other days.

On November 12th the Parliamentary Medical Committee met at the House of Commons; Dr. Alfred Salter was in the chair. After discussion, it was decided that in future the Committee shall consist solely of members of Parliament and peers holding medical qualifications, but that on questions where University members of Parliament without medical qualifications can assist the Committee they are to be invited to do so. University members have in previous Parliaments usually been added to the Committee. A suggestion that they should be made associate members was put forward, but was rejected. Holders of medical qualifications appear to number eighteen in the House of Commons and two in the House of Lords.

On the same date the Parliamentary Medical Committee further discussed the Medical Research Council and its constitution. The Committee's next meeting was fixed for November 26th, and Sir George Newman has been asked to address that meeting on the administrative control of small-pox and vaccination. The Committee has agreed to have an early discussion on diphtheria, and also to pay visits to health institutions, solaria, and the London refuse dumps.

Widows', Orphans', and Old Age Contributory Pensions Bill.

In the report stage of the resolution authorizing the expenditure needed for this bill, Major Elliot said that Mr. Greenwood and Miss Lawrence had never discussed, in its bearing on the bill, the report presented by the chief medical officer, Sir George Newman, on the state of the public health. Sir George referred to the changing character of the population, and the enormous burden which was going to be placed on the shoulders of the younger generations of this country as the old people became more numerous in proportion. At the beginning of the century there was a grandchild for every grandparent in the land, and by the middle of the century there would be two grandparents for every grandchild. In Major Elliot's opinion all available money should be concentrated on the children.

Dr. Morgan asked whether the figures given by the chief medical officer were not personal estimates.

Dr. W. E. Elliot said the fall in the birth rate and the fall in the death rate had consequences from which the House could not get away. There was nothing tentative about the number of children.

Miss Lawrence said that Dr. Elliot's figures were irrelevant. No part of the extra cost of the Government's proposals fell on the insured population. The tables showed that the increased expectation of life was chiefly between 50 and 60, when the bulk of the population was in productive labour.

The House agreed to the financial resolution.

Bills.

On November 11th Sir Robert Gower introduced a Housing Bill to make better provision for the improvement of unhealthy areas, to provide ade[illegible] business disturbance, and to make certain [illegible] to the Housing Act, 1925. The bill was r[illegible]

In the House of Commons, on November 12th, the Duchess of Atholl obtained leave to bring in a bill to amend the law regarding the duration and recovery of aliment for, and the custody of, illegitimate children in Scotland. She explained that the bill would empower the mother to make application for the expenses of her confinement, as well as for aliment, within three months of her expected confinement, although, if the case were defended by the father, the decree could not become operative until after the birth of the child. Among backers of the bill was Dr. Elliot.

Foot-and-Mouth Disease Research Committee.—On November 11th Mr. Buxton informed Rear-Admiral Beamish that the Foot-and-Mouth Disease Research Committee, set up in 1924, had already published three reports. The investigations which had been carried on during the past year at five laboratories had been on the lines described in the Committee's third report. Valuable additions had been made to the knowledge already acquired, and it was hoped that a further report on the work of the Committee might be published next year. It was still the policy of the Government to slaughter when disease broke out.

Medical Examination of Young Persons in Factories.—On November 12th Mr. Ben Turner told Dr. Vernon Davies that medical examination of young persons was now under consideration in connexion with a new Factories Bill. When this bill had become law, Mr. Turner would consider whether any change was necessary in mining legislation to bring it into conformity with factory legislation in this respect.

Ministry of Pensions Hospital, Cosham.—Mr. F. O. Roberts, replying to Colonel Clifton Brown on November 12th, said that he had not yet received the report of the committee set up to inquire into the affairs of the Ministry of Pensions Hospital at Cosham. He proposed to publish the report when received.

Accidents in Coal Mines.—Dr. Ethel Bentham, speaking on November 6th during the debate on accidents in coal mines, spoke of her early practice in a mining district where she had noted the incidence of accidents, fatal and otherwise. Once at a Labour conference she had observed that among eleven or twelve members of a mining delegation there was not one with a whole pair of hands—a missing finger, a smashed wrist, or other injury betokened a mining accident. There were at present 9,775 sufferers from nystagmus. Most members of the medical profession, she thought, agreed that posture and lighting conjointly were the causes, but it should be possible by concerted action to get real disinterested evidence thereon, and to put an end to a quite preventable disease. A motion for fuller protection of life in coal mines was agreed to.

Re-vaccination in the Navy.—On November 6th Mr. Alexander, answering Mr. Moses, said it had been the practice to carry out quinquennial re-vaccination in the Royal Navy when men were going abroad, and an order was issued on September 7th, 1928, that re-vaccination of active service personnel should be done every five years. No punishment was incurred for declining re-vaccination on conscientious or other grounds, but precautions were taken to prevent men not re-vaccinated from becoming a danger to the service by landing in ports where there was risk of small-pox. He did not propose to alter the regulations relating to recruits, as these were exposed to severe Oriental small-pox infection as soon as they went to sea, but the regulations about the vaccination of dockyard apprentices were under reconsideration.

Leaflets on Preventable Disease.—Asked by Mr. Somerville Hastings, on November 7th, whether he would provide leaflets on preventable human disease similar to those provided by the Minister of Agriculture on animal and plant diseases, Mr. Greenwood said that memoranda on human disease had been issued from time to time by his department, and would be further issued as occasion required. They were on sale to the public, but were primarily for the use of local authorities.

Royal Commission on the Civil Service.—Dr. Tremantle asked a question on November 6th, suggesting the addition of scientific representatives to the Royal Commission on the Civil Service. Mr. Snowden said that the terms of reference of this Commission had been widely drawn, and it would be for the Commission itself to determine the extent to which the various subjects could profitably be reviewed. He did not propose to enlarge its numbers.

Proposed School of Tropical Veterinary Science.—Mr. LUNN, replying to Mr. Ormsby-Gore on November 6th, said that the decision to establish a school of tropical veterinary science had been deferred until the report of the departmental committee on the reconstruction of the Royal Veterinary College at Camden Town was published. All the Colonial Governments had agreed to contribute towards the expenditure involved.

Disposal of House Refuse.—In reply to a number of questions asking when the report of the committee on the disposal of house refuse would be published, Mr. GREENWOOD said the committee's work had been delayed by the death of the chairman, Sir John Gatti. A new chairman would be appointed, and he saw no reason why the committee should not shortly publish its report. In reply to Dr. Fremantle and Mr. Mills, who asked about extensive refuse accumulations dumped in the Hatfield district and unhealthy conditions arising from open refuse destruction at Crayford, Kent, Mr. Greenwood said that any comprehensive action must wait for the committee's report.

Care and Management of Infants.—Replying to Mr. Somerville Hastings, on November 7th, Mr. GREENWOOD said it was the practice for local authorities to distribute booklets on the care and management of infants to the parents of every child when its birth was registered. This booklet was distributed by health visitors and at infant welfare centres.

Slum Clearance Schemes.—Mr. GREENWOOD told Commander Kenworthy that from 1925 to 1928 work was in progress on 118 slum schemes, some of which had been started prior to 1925. The total number of people rehoused was 71,413. In the case of 61 schemes the work of rehousing was completed during the period and provided accommodation for 20,745 persons.

Emission of Dust from Cement Works.—Replying to Mr. Mills, on November 11th, Miss LAWRENCE said that complaints had been received regarding the emission of dust from cement works on the banks of the Thames. An inspector of the Ministry of Health had made investigations, and steps had been taken to reduce the nuisance. The emission of fumes from cement factories was usually kept well in hand; dust gave the most trouble. Experiments were being conducted for dealing more effectively with it.

Risks of Asbestos Workers.—Mr. SHORT, replying to Mr. Stamford on November 11th, said that the risks to which those employed in asbestos works were exposed had been the subject of a comprehensive inquiry by the Factory Department. The Home Secretary hoped shortly to be in a position to consider what further precautions were necessary for the protection of the workers. Compensation would be considered at the same time.

Animals Slaughtered under the Tuberculosis Order.—On November 11th Mr. BUXTON informed Mr. Lowther that animals slaughtered during 1928 under the Tuberculosis Order of 1925 numbered 92 in Northumberland, 210 in Durham, 152 in Cumberland, and 320 in the North Riding. The carcasses of animals slaughtered, for which compensation was paid to the owner, became the property of the local authority, and the Order of 1925 (No. 2) provided that no parts of such carcasses should be removed for consumption without the written permission of the medical officer of health or other competent officer of the sanitary authority. Mr. Buxton was satisfied that proper precautions existed.

Cancer of the Bladder among Aniline Workers.—Mr. CLYNES, replying to Mr. Philip Oliver on November 7th, said he was arranging for the co-operation of the medical inspectorate of the Factory Department in the investigation of the industrial history of cases of cancer of the bladder among workers in aniline factories. He was also consulting the Registrar-General about supplying the statistical information concerned.

Notes in Brief.

Mr. Clynes stated, on November 7th, that efforts were being made to improve health conditions in spinning-rooms of artificial silk factories, particularly in the matter of eye injury and lung trouble. The remedy was efficient ventilation.

Mr. Clynes told Mr. Freeman, on November 7th, that no useful purpose would be served by additional records relating to vivisection, as stringent conditions were imposed in all cases where experiments were performed without anaesthesia or where the animal was allowed to come out of the anaesthesia.

Research into hysteria affecting sheep dogs is in progress at the Royal Veterinary College.

On March 31st last the number of blind men and women registered under the Blind Persons Act, 1920, in England and Wales, was 48,408.

On November 7th Mr. Herbert Morrison told Major Edmondson that it would not be practicable for voluntary hospitals to have a special legal claim to a proportion of insurance moneys paid to persons treated after motor accidents.

The total grant payable during the present financial year in respect of maternity and child welfare services is estimated at about £1,170,000, compared with £1,071,500 last year.

The Chancellor of the Exchequer cannot hold out any hope of adopting a suggestion that he should introduce legislation to provide that bequests to charities should only pay the same rate of death duties as bequests to near relatives.

The pollution of Scottish rivers is being investigated by a special committee.

A select committee on capital punishment is to be set up at an early date.

The Services.

DEATHS IN THE SERVICES.

Surgeon Commander John George Peebles, R.N. (ret.), died at Dinard on October 5th, aged 55. He was educated at Edinburgh, where he graduated as M.B. and Ch.B. in 1901, entered the navy immediately after, and became surgeon commander on February 8th, 1916. He served during the late war, receiving the medals.

Surgeon Captain Henry John Hadden, R.N. (ret.), died at West Moors, Wimborne, Dorset, on October 19th, aged 67. He was the elder son of the late Henry Richards Hadden, M.D., of Dublin, and was educated at Trinity College, Dublin, where he graduated as M.A., M.B., and Ch.B. in 1885. Entering the navy soon after, he attained the rank of fleet surgeon on February 18th, 1902, and after retirement was given an honorary step of rank as surgeon captain on January 24th, 1919. As surgeon of H.M.S. *Dolphin* he took part in the Eastern Sudan campaign of 1891, being present at the battle of Tokar, and received the Egyptian medal and the Khedive's bronze star. Previous to his retirement he was in charge of the naval hospital at Bermuda. During the late war he served as a temporary lieutenant-colonel in the R.A.F. Medical Service.

Staff Surgeon Henry William Melville Rees, R.N. (ret.), died after an operation on October 24th, aged 56. He was the only son of the Rev. W. Rees of Brnwydd, Llandilo, was educated at Owens College, Manchester, and took the M.R.C.S. and L.R.C.P.Lond. in 1893. Entering the navy soon after, he became staff surgeon on November 8th, 1906. After retirement he held the posts successively of medical superintendent of the treatment and training colony for discharged tuberculous ex-service men at Preston Hall, Aylesford; chief officer of the tuberculosis dispensary at Portsmouth; medical superintendent of Winsley Sanatorium, Bath; and tuberculosis officer for Pembrokeshire of the Welsh National Memorial Association.

Lieut.-Colonel Arthur Mercer Davies, R.A.M.C. (ret.), died recently at Eltham, aged 76. He was born at Westminster on September 17th, 1853, the son of the late Rev. Mercer Davies, was educated at Queen's College, Cork, and at Westminster Hospital, and took the L.S.A. in 1879, the M.R.C.S. in 1880, and subsequently the D.P.H. at Cambridge in 1889. Entering the army as surgeon on July 30th, 1881, he attained the rank of lieutenant-colonel after twenty years' service, and retired on September 17th, 1903. He served in the Egyptian war of 1882, gaining the medal and the Khedive's bronze star; in the campaign in the Eastern Sudan in 1884, when he was present at the battles of El Teb and Tamai (two clasps); and in the Nile campaign of 1884-85 (clasp). He was assistant professor of military hygiene in the Army Medical School at Netley from 1896 to 1902, and subsequently professor of the same subject at the R.A.M.C. College, Millbank, in 1906-8; and had also held the post of sanitary officer and bacteriologist at army headquarters in India. After retirement he served for a time as medical assistant in the Public Health Department of the London County Council. He was the author of a standard *Handbook of Hygiene*, which has gone through many editions, of *The Food of the Soldier* (1889), and of numerous reports and contributions on subjects connected with public health, military hygiene, and bacteriology. He married Evelyn, daughter of Captain David Aird, R.N., who survives him.

Lieut.-Colonel Willington Shelton Dowman, R.A.M.C. (ret.), died on September 2nd, aged 67. He was born on June 19th, 1862, was educated at Queen's College, Cork, took the Edinburgh double qualification in 1885, and entered the army as surgeon on July 28th, 1886. He attained the rank of lieutenant-colonel after twenty years' service, and retired on August 25th, 1906. He served in the South African war from 1899 to 1902, when he took part in the relief of Ladysmith and in the operations in the Orange River Colony, the Transvaal, and the Cape Colony, was mentioned in dispatches in the *London Gazette* of February 8th, 1901, and received the Queen's medal with four clasps, and the King's medal with two clasps. After his retirement he was employed as medical officer of the detention barracks at Cork in 1907-8, at Northampton from 1908 to 1912, and at Kingston-on-Thames in 1912. When war began in August, 1914, he was recalled from the Reserve of Officers to the active list, and served throughout the war, and after its close, as a district commissioner under the Ministry of Pensions.

Lieut.-Colonel Raghuber Dayal Saigol, Indian Medical Service, died at Beckenham on October 16th, aged 52. He was born on October 24th, 1876, and was educated at Lahore University, where he graduated L.M.S. in 1900, subsequently taking the Scottish triple qualification in 1901. Entering the I.M.S. as lieutenant on September 1st, 1902, he took the F.R.C.S.Ed. in 1903, and attained the rank of lieutenant-colonel on March 1st, 1922. He served in the Tibet campaign of 1903-4, receiving the medal. Before coming to England he held the appointment of ophthalmic surgeon to the general hospital at Rangoon.

Medical News.

THE Glasgow University Club of London will dine at the Trocadero Restaurant, Piccadilly, on Friday, November 29th, at 7.30 p.m., when the chair will be taken by Professor F. O. Bower, LL.D., F.R.S., president-elect of the British Association, and Sir Donald MacAlister will be the principal guest. Any Glasgow University men who, though not members of the club, desire to attend are requested to communicate with the honorary secretaries, 62, Harley House, N.W.1.

THE eighth annual dinner of the British Serbian Units Branch of the British Legion will be held at the Grafton Hotel, Tottenham Court Road, London, on Saturday, November 30th, at 7.30 p.m., under the presidency of Mr. Philip Mitchiner, F.R.C.S.

THE annual general meeting of the Old Epsomian Club will be held in the Oak Room at the Hotel Great Central on Thursday, December 12th, at 6.30 p.m., and will be followed by the annual dinner in the Marylebone Rooms of the same hotel at 7.15 for 7.30. The chair will be taken by Brigadier General G. T. Mair, C.M.G., D.S.O., and it is hoped that all Old Epsomians, whether members of the club or not, will be present on this occasion. The price of the dinner is 8s. 6d. (exclusive of wines). Attention is directed to the change of restaurants on this occasion.

AT the meeting of the Medico-Legal Society to be held at 11, Chandos Street, W.1, on Thursday, November 28th, at 8.30 p.m., Mr. F. Llewellyn Jones, M.P., LL.B., will read a paper on the League of Nations and the International Control of Dangerous Drugs.

A MEETING of the Royal Microscopical Society will be held in the lecture hall at 20, Hanover Square, W.1, on Wednesday, November 20th, at 8 p.m. Dr. J. A. Hewitt will read a paper on the sarcocystis in human heart muscle, and Mr. T. E. Wallis will describe the projectograph—an optical instrument for the projection of images of microscopical objects.

A MEETING of the London Clinical Society will be held at the London Temperance Hospital on Tuesday, November 19th, at 8.30 p.m.

MR. ALAN E. MUNBY, F.R.I.B.A., will deliver a lecture on the design of science buildings, at the Royal Institute of British Architects, on Monday, November 18th, at 8 p.m.

THE Joint Tuberculosis Council has arranged a post-graduate course in tuberculosis from November 25th to 30th, in the radiological department of the Brompton Hospital for Consumption. The provisional programme includes instruction in screening and diagnosis, with lectures on technique, the surgical aspects of tuberculosis, and dental radiography. The fee for the course is three guineas. Further information may be obtained from Dr. William Brand, honorary secretary of the post-graduate courses of the Joint Tuberculosis Council, 1, Gordon Square, W.C.1.

UNDER the auspices of the Fellowship of Medicine a lecture, free to medical practitioners, will be given on haemorrhoids, at 11, Chandos Street, Cavendish Square, on Monday, November 18th, at 5 p.m., by Mr. Mortimer Woolf. On November 19th, at 8.30 p.m., Dr. Langdon Brown will lecture at the same place on recent advances in endocrinology. On November 18th, at 2.15 p.m., Dr. A. J. Whiting will conduct a "ward round" at the Prince of Wales's General Hospital, Tottenham. Mr. A. D. Griffith will give a special demonstration, free to medical practitioners, at the Royal Eye Hospital at 3 p.m. on Wednesday, November 20th. Two special courses begin on November 18th: the first, a whole-day course, at the Royal National Orthopaedic Hospital, will last for two weeks; the second is a four weeks' course at the West End Hospital for Nervous Diseases, which [illegible] demonstrations illustrated by cases, a [illegible] at 5 p.m. An all-day course in procto[illegible] t. Mark's Hospital from November 25th to 30th. Three courses will be given in December: one in diseases of infants at the Infants Hospital, on afternoons only, from December 2nd to 14th; one in dermatology at the Hospital for Diseases of the Skin, Blackfriars; and a general practitioners' course at the London Temperance Hospital from 4.30 to 5.45 p.m. Detailed syllabuses of all courses, the advance list of special courses for 1930, and particulars of the general course arranged by the Fellowship at its associated hospitals, may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

DR. ROBERT FELL, who has been senior anaesthetist at the York County Hospital for twenty years, and has lately retired from the active staff, was entertained at dinner last week by his colleagues. Dr. Evelyn, senior physician to the hospital, was in the chair, and after dinner Dr. Fell was presented with a silver salver.

THREE historical surveys, illustrated by lantern slides, will be given by Dr. Charles Singer at University College Hospital Medical School on Mondays at 4.15 p.m.: (1) dominance of the nervous system in the body, November 18th; (2) biogenesis and infectious disease, November 25th; (3) essentials of heredity, December 2nd. The lectures are open to all medical students of the University of London.

Dr. F. A. L. BURGES, M.B.E., has been appointed chairman of the Birmingham Insurance Committee.

THE following members of the medical profession were among the mayors elected on November 9th: Dr. R. F. Bury (Leamington Spa), Dr. C. Grey-Edwards (Poole), Dr. S. W. Jeger (Shoreditch), Dr. I. G. Modlin (Sunderland, re-elected), Dr. L. E. Price (Nuneaton, re-elected), Dr. H. Robinson (Kensington, re-elected), Dr. F. P. Rose (St. Ives, Hunts), Dr. C. S. Spencer (Ashton-under-Lyne).

THE KING has granted authority to Dr. Herbert Chavasse Squires to wear the Insignia of the Third Class of the Order of the Nile, conferred upon him by the King of Egypt in recognition of valuable services rendered.

THE Minister of Agriculture and Fisheries has issued draft regulations under the Agricultural Produce (Grading and Marking) Act, 1928, defining grade designations for voluntary use in connexion with malt flour and extracts prepared entirely from home-grown grain. Two grades of all-English malt flour are prescribed for use in baking white and brown bread respectively, and four grades of all-English malt extract—namely, "pharmaceutical," "bakers (white bread)," "bakers (brown bread)," and "veterinary." A scheme, which is supported by the Association of Malt Products Manufacturers, will come into operation on December 1st to give effect to these regulations. In each grade of malt flour and extract a standard of diastatic power is defined and certain other factors are also prescribed, such as the protein content and specific gravity of extracts, and the moisture or fibre content of the flour. A "national mark" will be applied to the packages in which these products are supplied; they are commended to the notice of medical practitioners, bakers, and pharmaceutical chemists who require standardized products. The regulations are published by the Stationery Office (price 2d.), and a leaflet explaining the scheme (Marketing Leaflet No. 14) can be obtained free of charge on application to the secretary, The Ministry of Agriculture and Fisheries, 10, Whitehall Place, S.W.1.

AN international committee for the study of infantile paralysis has been formed in New York under the presidency of Dr. W. H. Park. The scientific institutes chosen for centres of research are the Universities of New York, Chicago, and Cambridge, Mass., in the United States, and the Lister Institute, London, and Institut Pasteur of Brussels in Europe.

THE Alvarenga prize for 1929 has been awarded to Dr. G. M. Dorrance of Philadelphia for an essay entitled "Congenital insufficiency of the palate." The College of Physicians of Philadelphia announces that the next award of this prize, amounting to about 300 dollars, will be made on July 14th, 1930. Essays must be received before May 1st, 1930, by the secretary of the college, 19, South 22nd Street, Philadelphia, from whom further information may be obtained about the conditions prescribed.

THE new extensions of the Hampstead General and North-West London Hospital were opened by the Duchess of York on November 7th. The building includes an operating theatre, a dispensary, casualty department, additions to the pathological laboratory, a lecture theatre for nurses and post-graduates, additions to the accommodation of the resident medical staff, and a block of emergency beds.

THE October issue of *The Cripple* contains an account of the proceedings and results of the first international conference, which was held at Geneva at the end of July. A paper read by Dame Georgiana Buller at the conference, on the care of crippled children, is included, and also the address delivered by the president of the International Society for Crippled Children on the evolution of the problem of the cripple. Massage as a profession for the blind is discussed by Mrs. Chaplin Hall, secretary of the Association of the Certified Blind Masseurs. This periodical can be obtained from the publishers, John Bale, Sons, and Danielsson, Ltd., 83, Great Titchfield Street, W.1, at the price of 2s. per copy; the annual subscription is 8s.

THE second international congress of malaria will be held at Algiers from May 19th to 21st, 1930, under the presidency of Dr. E. Marchoux. Further information can be obtained from the secretary, Institut Pasteur, Algiers.

A MEMORIAL tablet has recently been placed on the house of Dr. Aloys Pollender (1800–79) at Wipperfürth, Westphalia; he described the anthrax bacillus in 1849, a year before C. J. Davaine, who is generally credited with its discovery.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to *The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.*

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The *TELEPHONE NUMBERS* of the British Medical Association and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563,* and *9564* (internal exchange, four lines).

The *TELEGRAPHIC ADDRESSES* are:
EDITOR, of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

Trauma to the Testicle.

"First Aid" writes: Can anyone suggest a method of relief for a blow upon the scrotum, such as may occur on the football field? I have been told that turning the patient on to his elbows and knees and giving firm pressure with the hand or a pad to the scrotum and anal region has been useful. Later, probably cold water or ice applied would be best.

Sensation of Asphyxia due to Ethyl Chloride Inhalation.

"W. D." writes: I frequently give anaesthetics for big operations and dental cases with Clover's apparatus, first spraying into the bag ethyl chloride, and following on with ether in the usual way. I find that most patients object to the first part—namely, the ethyl chloride—saying that they feel suffocated. Can any reader give advice?

Treatment of Emphysema.

"A. J." asks for information, based on personal experience, about the use of intramuscular injection of quinine and camphor dissolved in ethereal oils in the treatment of fairly long-standing emphysema.

Spa Treatment of Arthritis.

DR. W. E. KINGDON (Leominster) asks for information concerning spa treatment for rheumatoid arthritis at Freiburg in Breisgau.

Income Tax.

Payment of Interest.

"A. T. B." bought a house in January, 1925, borrowing part of the purchase price from a bank. In June, 1927, he purchased another house, borrowing £1,850 from an insurance company. What is his position as regards payment of interest?

*** So far as the bank interest is concerned he is entitled to treat it as a deduction in arriving at his liability. If that has not been done, so that that interest has in law been paid out of his taxed income, he is entitled to a repayment or some equivalent set-off. On the other hand, the position with regard to the insurance company's interest is entirely different. In that case the company has allowed him to deduct the tax on payment of the interest. For instance, in April, 1929, instead of paying £26 0s. 4d., the gross amount of interest due, he paid that amount *less* the appropriate income tax, £5 4s. 1d., and the latter sum represents tax due to the Crown, but which at present is in his hands, to be paid over when due. The statement enclosed with "A. T. B.'s" letter sets out the total amount which will have become due in that way for the three years ending April 5th, 1930, and appears to be correct, except that it does not take into account the set-off for the bank interest, which will be due unless it has already been received in some other way.

Change in Nature of Work.

"R. L. B." held two hospital appointments during 1928–29, from which he received in all £130. During 1929–30 he is employed as an assistant in private practice at £350 a year. Can he claim to be assessed on the basis of the income of the previous year 1928–29?

*** No. The change in the nature of the work and terms of engagement are such as to require the income of 1929–30 to be treated as derived from a new appointment, and he is assessable for that year on the actual year's basis.

LETTERS, NOTES, ETC.

Radium Technique.

DR. L. A. ROWDEN (Leeds) writes: Dr. Douglas Webster, in speaking on radium therapy in the discussion by the Medical Society of London, as reported in the *British Medical Journal* of November 2nd (p. 807), pointed out the value of radium applied from a distance, and said "he believed he was the first worker in this country to use it in that way." Since as far back as 1903 it has been my custom to apply radium in certain cases 2½ in. to 3 in. from the skin the idea of a radium "bomb" is by no means new.

The Jamaica Health Campaign.

"M. M." writes: Little notice has been taken in this country of the remarkable work achieved, and still in progress, in Jamaica by the Rockefeller Institute. This work began with a campaign against hookworm, the greatest general destroyer of health and energy in many tropical areas, and has of late gone on to the investigation of problems connected with malaria and tuberculosis. In Jamaica the leading figure in this struggle against disease has been Dr. B. E. Washburn, who, after more than ten years' successful fight against almost impossible conditions, is now in London taking a post-graduate course in tropical medicine. As a director of health [illegible] merit, apart from the actual [illegible] areas, has been his success in [illegible] in such a way as to begin the [illegible] conscience. To do so much meant the replacement of ancient and futile "bush-tea" superstitions by plain teaching and gentle ridicule. This has been done in his *Jamaica Health Stories and Plays*, published by the Jamaican Government, a volume which has attracted attention in many countries and has already been translated into Spanish for use in Central and South America. Whatever success has been attained by the able band of workers who labour under the aegis of the Rockefeller Institute, it seems no small reflection on our own colonial authorities that the task should have been left to America; but however that may be, we owe the greatest thanks to Dr. Washburn and his co-workers, and are happy to say as much while he is among us.

Medical Golf.

A WEEK-END meeting of the London Irish Medical Golfing Society was held recently at Sandwich, when more than sixty members were present. An auction sweep was held in connexion with the meeting, and proved to be a great success; 11 guineas were sent as a donation to Epsom College. The results of the competition were as follows:

The Canny Ryall Cup.—1st, E. T. Wright, 74 (77–3); 2nd, D. R. Wheeler, 76 (86–10); 3rd, J. A. Pringle, 82 (87–5); 4th, R. L. Rea, 82 (96–14); 5th, W. MacAuley 83 (93–10); 6th, A. Perry, 83 (97–14); 7th, J. E. Ambrose, 83 (105–20). There were 63 entries, and 40 cards were returned.

The O Malley Cup.—1st, E. T. McElligott (7) and C. Petit (20) tied, 1 up; 2nd, E. S. A. Crawford (20), all square; 3rd, F. Salter (9) and E. Ryan (14), both 1 down; 4th, A. G. Walsh (4), T. J. Kelleher (12), and W. K. Calwell (16), all 3 down. C. Petit won the cup on a replay. There were 59 entries, and 47 cards were returned.

The Tett Cup.—1st, D. S. Gordon and E. T. Wright (5), and E. S. A. Crawford and C. L. Wilson (34) tied, 3 down; 2nd, J. S. Gubbins and E. Ryan (32) 4 down; 3rd, J. Corcoran and C. Petit (33) 6 down. D. S. Gordon and E. T. W[illegible] there were 28 entries.

The Cahill Trophy.—1st: [illegible] T. Wright, 159; 3rd, C. Petit, 169; 4th, E. [illegible]

The Captain's Prize.—1st, E. T. Wright, 36; 2nd, A. G. Walsh and D [illegible] 36; 2nd, R. J. Maybury and P. Coffey tied, 38.

Eclectic Competition.—W. Calwell and D. R. Wheeler tied.

The annual dinner of the society and the presentation of cups took place on November 14th at Pagani's Restaurant, Great Portland Street.

Night Assistance for Motorists.

MEDICAL members of the A[illegible] may be glad of a reminder that up-to-date [illegible]oads, or districts in which fog [illegible]n the twenty-four-hour emergen[illegible]ndon W.1 A.A. headquarters, Fanum [illegible] (Regent 8000).

A Warning.

DR. JEAN DOLLAR (house-surgeon, Royal Eye Hospital, Southwark) writes: A man visited this hospital one evening lately and asked for the medical superintendent. He gave his name as Dr. W——, and refused to state his business, except to me. He told a rambling story, with considerable histrionic talent: He had been three years in Maidstone gaol, struck off the *Register*, trying to get a job as dispenser, etc., and finished with a request for monetary assistance. I have since ascertained that he attempted to extract cash from a former woman house-surgeon with the same story. I imagine he makes a circular tour of the smaller hospitals every six months.

Vacancies.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 53, 54, 55, and 56 of our [illegible] assistantships, and [illegible] pages 50, 51, and 52.

[illegible] as to partnerships, advertisement colun[illegible] in the advertisement

A short summary [illegible] columns appears in the *Supplement* at page 227.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

425. The Refractory State of the Heart.

LUTEMBACHER (*Bruxelles-Médical*, August 4th, 1929, p. 1106) considers the changes produced in the refractory period of the heart muscle and its conducting system by pathological processes. At the beginning of diastole the bundle of His is momentarily incapable of conducting another impulse, and when its tissue is the seat of disease this refractory period increases, and is shown by the prolonged PR interval and missed beats in the electro-cardiogram. Cases have been described in which acceleration of the sinus rhythm—as, for example, by change of position or exercise—has produced greater incapacity of the conducting system so that the pulse rate progressively falls. A similar phenomenon is found when the branches of the bundle are attacked, extrasystoles and auricular tachycardia unmasking various defects in conduction. These facts are of practical importance since they indicate latent defects in conduction and explain certain harmful results of drug administration. If the refractory period of some of the fibres of the myocardium is prolonged by disease the condition known as alternation is produced, weak and strong beats alternating, since the damaged fibres contract only with every other beat. An explanation based on the prolongation of the refractory period is also offered to explain auricular flutter and fibrillation; the fibres do not recover simultaneously from their refractory state. Accordingly they recover in successive groups, causing circus movement in the first case, and independent fibrillary contractions when the myocardium is more severely injured. The author has studied the transparent embryonic heart and has been able to demonstrate the effect of calcium chloride in producing phenomena comparable to alternation and fibrillation.

426. Nickel-platers' Rash.

K. GRON (*Urol. and Cut. Review*, September, 1929, p. 606) states that Blaschko in 1889, when speaking of "galvanizers' eczema," was the first to draw attention to the injurious effects of the nickel bath on the workman. The form in which the eruption usually appears does not differ to any great extent from the other occupational dermatoses due to local irritation by salts of heavy metals. After an initial stage of itching a dermatitis consisting of small papules and vesicles develops. Pyodermic and impetigo-like areas are frequent, and in exceptional cases may lead to superficial gangrene. The eruption tends to affect previously existing cracks and scratches due to mechanical or chemical trauma. The favourite sites are the hands and forearms, but the rash may appear on the lower part of the face and neck, upper part of the chest, lower extremities, and genitals, while in exceptional cases it may be widespread. As a rule there are no general symptoms apart from itching, but occasionally the patients suffer from feverishness, pains in the joints, limbs, and chest, and headache. Several of Gron's patients had stomatitis and gingivitis. The incubation period ranges from eight days to two months. Females are more frequently affected than males, and the eruption may undergo exacerbation during the menstrual period. The duration of the attack is from one to two weeks up to several months, but recurrences are frequent. Prophylaxis consists in rubbing into the skin an ointment composed of lanolin, boric acid, and zinc peroxide. Calcium chloride by mouth is employed to restrict the increased alkalinity of the blood caused by extreme heat.

427. Incidence of Chronic Articular Rheumatism in Sweden.

G. KAHLMETER (*Nordisk Medicinsk Tidsskrift*, September 7th, 1929, p. 570) claims that the first investigation showing the incidence of chronic articular rheumatism in a country was that undertaken in 1920 by the Swedish Ministry of Pensions, whose statistics dealt with the year 1918. In that year old age and arterio-sclerosis accounted for 55 per cent. of all persons drawing invalidity persons. Next in the order of frequency came articular rheumatism with 9.1 per cent.; pulmonary tuberculosis with 5.8 per cent.; and diseases of the stomach and intestines, including gastric carcinoma, with 3.3 per cent. The figures for all the other ailments qualifying for pensions were much smaller. In Sweden every year about 3,000 patients become entitled to receive pensions on account of permanent disablement due to articular rheumatism; the total number of patients drawing pensions for this reason is about 35,000, and the total sum they receive yearly is about five million kroner. With regard to the importance of providing institutional treatment for such cases, and to the strictly economic returns to be obtained from such treatment, the author reviews the results of the institutional treatment given to 975 patients in the period 1915 to 1923 in the establishments of the Ministry of Pensions. It was found at the end of 1925 that 62 per cent. of these patients had improved so much that they were able to maintain themselves completely or almost so.

428. Agranulocytosis in Diphtheria.

C. FARMAKIDIS (*Presse Méd.*, August 28th, 1929, p. 1121), who records seven illustrative cases in patients aged from 7 months to 35 years, states that systematic examination of the blood and leucocyte count in his diphtheria wards revealed a number of cases presenting the features of agranulocytosis—namely, very pronounced leucopenia, with almost complete disappearance of the polymorphonuclears, *increase in number of the blood platelets, and no important* changes in the number and quality of the red cells. He considers it a remarkable fact that with one exception all the patients recovered; this confirms the statement of Aubertin and Lévy that the more that is known about agranulocytosis, the greater will be the number of patients found to recover, in accordance with the well-known fact that in the case of a new disease the most severe forms are the first to be recognized.

429. The Kidneys in Diabetic Coma.

I. M. RABINOWITCH (*Canadian Med. Assoc. Journ.*, September, 1929, p. 274) points out that the renal function in diabetes mellitus differs in no way from that found in normal individuals, providing that the disease is kept under control. In the absence of proper treatment, with persistent glycosuria and hyperglycaemia, cardio-vascular-renal changes may occur. The disturbances of kidney function in diabetic coma may be summarized briefly as follows: (1) No albuminuria (no disturbance); this is extremely uncommon. (2) Albuminuria, with or without urea retention. When urea retention is present the course of events may be as follows: recovery to the normal level after the acidosis has been controlled; or progressive impairment for some days with eventual recovery; or progressive impairment leading to uraemia; but even with uraemic symptoms the patient may recover. A guarded prognosis is necessary when, in the absence of hypoglycaemia, drowsiness persists in spite of the disappearance of the acetone from the breath and urine, and when the blood of such patients shows marked urea retention. In diabetic coma, as in all acute lesions of the kidney, a positive diazo-reaction does not necessarily indicate an unfavourable prognosis.

430. Gonococcal Vertebral Arthritis.

V. FOSSATI and A. TORRE (*Rev. Sud-Amer. de Endocrinol., immunol. y quimioterapia*, August 15th, 1929, p. 582), who record two illustrative cases in men aged 67 and 52 respectively, the first of which was fatal, state that gonococcal arthritis of the vertebral column is a rare disease which may have a fatal termination. The diagnosis is facilitated by the presence of the gonococcus in the genital tract and the subsequent characteristic complications, while the patient's age and denial of a history of contagion should not prevent a close examination being made. The course is subacute. In the first case death ensued from mechanical compression after four months' illness, while the second patient made a rapid recovery after injections of gonococcal nucleoprotein.

431. Prophylaxis against Measles.

G. B. BADER (*Journ. Amer. Med. Assoc.*, August 31st, 1929, p. 668) reviews the literature and reports on 30 infants, aged from 6 to 32 months, exposed to measles, who were injected intragluteally with 20 to 30 c.cm. of whole blood from adults who had had the disease two to twenty-five years previously. The results were as follows. The blood which was given within the first seven days after exposure completely protected 12 infants, and partially protected 9 who had a modified attack without catarrhal symptoms and 8 who had mild catarrhal symptoms. One child, who was the only one to have Koplik's spots and a typical eruption, had a moderately severe attack; in the remainder, when eruptions were present they were not characteristic. The temperature

was distinctly modified except in two instances; the incubation period was prolonged in all but four. There were no complications. Bader suggests that this method of injection of the whole blood of adults long recovered from measles would be particularly suitable for institutions where cross infections often occur and serum from recently convalescent patients is not readily available; or in children under the age of 5, in whom 90 per cent. of the deaths from measles occur; or in the weak and debilitated, in whom measles might cause a fatal issue.

432. The Incubation Period of Paratyphoid B Fever.

E. SYLVEST (*Ugeskrift for Laeger*, July 11th, 1929, p. 593) records the case of a girl, aged 9, who, between 1 and 4 p.m. on April 7th, visited her aunt whom she had not met for a long time, and shook hands with her both when coming and going. During the three hours' visit the child went to the w.c. On her way home in the tram the child complained of severe headache, and in the evening of the same day her temperature was 102°. Widal's reaction was positive, and paratyphoid B fever was diagnosed. On the morning of April 11th, barely four days after the niece's visit, the aunt felt unwell and chilly, and when she went to bed on April 16th, feeling very ill, her temperature was 103°. On April 27th Widal's reaction was positive, and paratyphoid B fever was diagnosed. In the period under review only three cases of paratyphoid fever were known in the whole of Copenhagen, and the aunt's case was the only one in her town. The author suggests that the niece had soiled her hands during her visit to the w.c., and that she infected her aunt simply by shaking hands.

433. Frequency of Non-Diabetic Glycosuria.

H. J. USTVEDT (*Norsk Mag. f. Laegevid.*, September, 1929, p. 950) found that among 10,000 patients without any symptoms of diabetes, glycosuria was present in from 1 to 2 per cent. Half the cases of glycosuria discovered by chance proved to be due to diabetes. In 27 per cent. of 240 cases of diabetes the disease was not diagnosed until after admission to hospital. Of 62 cases of chronic glycosuria discovered by chance 55 were due to diabetes. Among 206 cases of chronic glycosuria, including those due to diabetes, there were only 2 examples of renal glycosuria and 5 of glycosuria with cyclical hyperglycaemia; 14 out of 32 cases of transient glycosuria were connected with cerebral affections. It appears that glycosuria is most readily produced by those cerebral affections which have a sudden onset, especially subarachnoid haemorrhage. Occasionally severe hæmatemesis is followed by glycosuria and slight and transient hyperglycaemia. Ustvedt has seen three examples of renal glycosuria—in a woman and her two daughters—and instances of transient glycosuria in a brother and sister.

Surgery.

434. Treatment of Renal Lithiasis.

W. C. QUINBY (*Amer. Journ. of Surg.*, August, 1929, p. 234) emphasizes the importance of infection and stasis in the production of renal stone, though cases of lithiasis do occur in which the calculi are formed in a sterile kidney. Treatment should aim at restoring the normal conditions within the kidney, besides removing the stone. In view of the great damage done by a renal calculus involving the ultimate destruction of the kidney, every case should receive attention [illegible] been diagnosed. In the absence of [illegible] all renal calculi which, on account [illegible] sed through the normal channels, should be extracted by an operation which must aim at the removal of the stone with as little destruction of renal tissue as possible and with free drainage assured. In severe cases this can be effected by means of a tube which enters the pelvis through a nephrotomy opening. A free mobilization of the kidney, and the use of *x* rays at the time of operation, indicate the best method of dealing with each case, the simplest attack on the kidney being pyelotomy; a more severe method is pyelonephrotomy, and the most severe an extensive nephrotomy. Nephrectomy should only be performed in cases where the kidney has become valueless through disease. After all obvious stones have been removed, a further *x*-ray examination should be employed to make sure that no particles remain to serve as the nucleus of a subsequent stone. Out of a series of 226 cases there was no operation in 10 per cent., nephrectomy was necessary in 11 per cent., and pyelotomy or pyelonephrotomy in 77 per cent. of cases. There was an operative mortality of 3½ per cent.

435. Toxic Conditions of the Thyroid Gland.

ACCORDING to N. CANTO (*Arch. de med., cir. y esp.*, September 7th, 1929, p. 235) thyroid toxicosis is a very rare disease in Spain, only two cases of operations on toxic thyroid glands having been published in the last two years. Compared with the very large American statistics this is all the more remarkable, for the proportional incidence of other diseases is much the same in both countries. Actually, even in the big Swiss clinics such as de Quervain's, the incidence of toxic goitre seems to be less than in the States; so that probably thyroid toxicity is less frequent in Europe than in America. Canto thinks that perhaps this is to be correlated with the emotional intensity of American life. It has been said that toxic goitre occurs principally in the endemic goitre districts; Spain has such regions, and could therefore be expected to produce a considerable amount of Graves's disease, and latterly investigators of basal metabolic rates have been discovering many cases. Especially amongst army recruits many persons have been discovered having tachycardia without any other cardiac physical sign, and the author thinks that estimations of the metabolism would probably show that in many of these the condition is due to hyperthyroidism. According to Hertzler in less than 10 per cent. of toxic thyroid cases is there exophthalmos, and it is well known that the thyroid gland is not always perceptibly enlarged. It is therefore concluded that the disease is probably not rare, but the low figure recorded is due to the fact that medical practitioners hesitate in making such a diagnosis because of an incomplete clinical picture; Canto advises that more numerous estimations of the metabolism would clear up the difficulty. He believes that the facts about thyroid disease should be published more widely and the warning given that 95 per cent. of thyroid carcinomata arise in the apparently harmless adenoma.

436. Separation of the Symphysis Pubis.

J. C. WISHNER and L. MAYER (*Surg., Gynecol. and Obstet.*, September, 1929, p. 380) divide separations of the symphysis pubis etiologically into those caused by severe external trauma (rare) and those occurring during parturition; they record six cases. They consider that it occurs more often during parturition than has been supposed, its apparent rarity being due to lack of recognition of the symptoms—pain, palpable separation, difficulty in walking, and a waddling gait due to instability of the pelvic arch and weakening of the sacro-iliac joints; and, in a less degree, to the posterior displacement of the hip-joints, which face laterally instead of antero-laterally. Functional cure is possible even though a slight separation of the symphysis demonstrable by *x* rays may persist. Treatment aims at correcting the three pathological lesions—namely, the separation of the symphysis, the corresponding gaping of the anterior portion of one or both sacro-iliac joints, and the posterior displacements of the hip-joints. By the application of a powerful circular compression to the pelvis the pubic bones are approximated, the gaping sacro-iliac joints are closed, and the acetabula restored to their normal place. With the patient in bed a canvas swathe 6 to 8 inches in width completely envelops the pelvis from behind forwards, extending 8 or 10 inches beyond the body on either side, the ends being attached to spreaders to prevent wrinkling. A rope from each of these runs over pulleys on each side of the bed carrying weights commencing with 5 lb. and rapidly increasing to 25 lb.

437. Surgical Treatment of Pulmonary Tuberculosis.

E. ARCHIBALD and M. ISELIN (*Arch. Méd. Chir. de l'Appariel Respirat.*, March, 1929, p. 128) discuss the surgical treatment of phthisis based on an experience of 167 interventions practised in the last nine years. The operations were either total thoracoplasty or phrenectomy when there was doubt about the resistant capacity of the more sound lung, or as a preliminary or substitute for the more severe operation. Three main groups of cases are concerned: uncomplicated parenchymatous tuberculosis; phthisis complicated by an artificial pneumothorax; and tuberculosis associated with purulent pleurisy. The authors classify their cases as good, doubtful, and bad from the operative point of view. The good case is one where the disease is mainly unilateral and fibrotic, with only minute cavities and no progressive lesion on the other side. Signs of retraction and absence of benefit from pneumothorax stamp the case as doubtful; and bad cases show still more unfavourable signs. Out of 30 good cases operated upon the ultimate results were traced in 24; of these, 16 patients were "practically cured," 4 much improved, one moderately benefited, and 3 died—one from typhoid fever, one from broncho-pneumonia three years later, and one from an unknown cause. The operative mortality was therefore 4.2 per cent. "Practically cured" implied that there were no active signs or symptoms for a year, no cough, only slight mucous expectoration, no bacilli, and

resumption of work. Of the doubtful cases, 17 out of 45 were cured and 9 patients died. Of the 21 "bad cases," none were cured, but 3 were much improved, 4 moderately benefited, and 14 patients died. In 9 cases thoracoplasty was performed to remedy unsatisfactory pneumothorax results, and 4 of these were cured. The worse results were obtained in the purulent pleurisy cases, especially where secondary infection existed. Taking all the cases, excluding the purulent pleurisies, the operative mortality was 11.6 per cent., but 37 per cent. were cured.

433. Surgical Treatment of Cardiac Disorders.

IN view of the risk entailed and the poor results obtained in spite of careful technique in cases in which an attempt has been made to operate on the heart, W. FELIX (*Deut. med. Woch.*, September 13th, 1929, p. 1541), in a number of animal experiments, tried to influence the artificially damaged organ by extracardiac surgical manœuvres. The return of blood depends to some extent on the intrathoracic pressure, and the functioning of a diseased as of the normal heart is affected by the external pressure brought to bear on it; this pressure is the resultant of a number of forces, including the tension of the thoracic wall, the elasticity of the lungs, and the intrapericardial pressure. A moderate amount of dilatation (with hypertrophy) compensates certain valvular lesions, and Felix found that this dilatation was facilitated and accelerated in experimental animals when pressure on the heart was reduced by extensive pericardiotomy; this produced a beneficial effect on the blood pressure, pulse amplitude, and the cardiac output in several cases in which acute and chronic tricuspid and mitral insufficiency had been artificially produced. In other valvular lesions the response to diminution of the extracardiac pressure was less constant. Making folds in the pericardium, or diminishing the elastic pull of the lung by paralysing one side of the diaphragm, was found to produce a relative increase of pressure on the heart with diminution of its activity; this caused delay or prevented dilatation in a number of rabbits in which a chronic rise of blood pressure had been produced by severing certain nerves. Felix emphasizes the point that the work is still in the experimental stage, but he thinks that the results obtained are sufficiently promising to justify further investigations along similar lines.

439. Chronic Prostatitis.

J. W. VISHER (*Med. Journ. and Record*, August 21st, 1929, p. 214) discusses the role of chronic prostatitis in the etiology of sacro-iliac and spinal arthritis, having observed a definite correlation between them. From anatomical considerations he believes that the infection extends by way of the lymphatics from the prostate to these joints, the lymphatic drainage of the prostate being to the glands lying in the hollow of the sacrum and beside the bodies of the lumbar vertebrae; it is probably by this route that early metastases in carcinoma of the prostate travel to the sacrum and vertebrae. In a statistical study of 500 ex-service men it was found that 87 (17 per cent.) presented definite clinical and laboratory evidence of prostatic involvement; radiograms of the spine and sacro-iliac regions of 35 of these showed definite [illegible] eo-arthritis in 20 (55 per cent.). for proof, Visher submits the y spread by way of the lymphatics to the spine and sacro-iliac bones, and he points to the necessity of making a careful prostatic examination, including examination of the expressed secretion, in every man complaining of backache, sciatica, or vague pelvic pains.

Therapeutics.

440. Treatment of Cystic Osteo-fibrosis.

H. VERGER, P. DELMAS-MARSALET, and P. BROUSTET (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, August 30th, 1929, p. 673) describe the successful treatment of a case of Recklinghausen's cystic osteo-fibrosis. A single woman, aged 36, was admitted to hospital in May, 1928, for inability to walk; she had held a responsible post involving work in a close office shut off from sunlight. In April, 1925, she sought advice for "neuritic" pains in the thighs, which were at first thought to be the result of a severe anaemia, and she had been advised to undergo treatment by rest and sunlight. In November, 1925, however, she returned with the pain much worse, and in a generally ill-nourished and feeble state; there was a palpable enlargement of the upper end of the left femur, and an *x*-ray examination revealed vacuolation of bone at the upper ends of both femoral diaphyses; a spontaneous fracture of the left femur occurred soon afterwards, and a further *x*-ray examination showed vacuolation also of the right radius and ulna and both tibiae. She was kept immobilized for eleven months, and general treatment was given by ultra-violet light, calcium salts being administered by the mouth. Union of the fracture ensued and there was great improvement in the general health, but on discharge from hospital and resuming work the patient stopped all treatment. Pain and difficulty in walking began again soon, and there was now also pain in the right hand. On her readmission to hospital in May, 1928, an *x*-ray examination showed general osseous decalcification and a series of vacuoles affecting most of the long bones, the cranium, and probably the pelvis; the bony tissue was reduced in places to a mere shell, especially where the fracture had taken place. Treatment was begun by ultra-violet irradiation of the lower extremities, with relief of pain, but an *x*-ray examination in July showed no change. From August 1st onwards 50 drops daily of irradiated ergosterol were given, and three times a week an injection of 1 gram of calcium gluconate. Gradually she regained her former health, and she was able to walk again; an *x*-ray photograph showed commencing regeneration of bone, and in February, 1929, a general regeneration; by this time her health was satisfactory and she could walk well. The authors regard the case as an example of associated calcium and sunlight deficiency, and attribute the improvement under treatment to the administration of calcium coupled with vitamin D as a calcium fixative, in the form of irradiated ergosterol. It is stated that since the writing of these notes the patient has developed a benign tumour of the iliac crest, which proved on biopsy to contain giant cells and bony lamellae; it is regarded as being caused by the same process as the cysts already described.

441. Potassium Permanganate in Acute Respiratory Infections.

C. S. MURRAY (*New Zealand Med. Journ.*, August, 1929, p. 229) records his experience in the treatment by rectal injections of potassium permanganate, not only of lobar pneumonia, but also of other acute respiratory conditions. Notes of five cases are given in which the sudden change from a toxic to a non-toxic state was so remarkable that he regards the injections as being the sole factor in producing the sudden improvement. The fall in temperature was accompanied by a distinct sense of well-being, and the clinical picture and general appearance of the patient changed in a few hours from that of acute illness to one of established convalescence. This was generally associated after two or three days with the appearance of a healthy rosy tint in the previously pale cheeks, a change of colour which has been noticed by the author in other cases (as, for example, two patients with chronic colitis) receiving rectal injections of potassium permanganate. These effects resulted in every instance, whether the condition was a lobar pneumonia, a mixed influenzal and pneumococcal or a haemolytic streptococcal infection, or an influenzal lobular pneumonia. A rectal injection of 1 grain of potassium permanganate in 5 oz. of water is given once or twice daily for five or six days; if there is inability to retain this satisfactorily, two-hourly injections of 1 oz. of the solution may be given, with gradually increasing strength and intervals. The author points out that the fact that the potassium permanganate acts irrespectively of the type of infection renders it useful in those cases of pneumococcal infection other than Type I where serum is of value.

442. Treatment of Pruritus Ani.

ACCORDING to F. C. YEOMANS, R. V. GORSCH, and J. L. MATHESHEIMER (*Med. Journ. and Record*, September 4th, 1929, p. 279), all cases of pruritus ani fall into four groups: those due to a constitutional cause, such as gout, rheumatism, or diabetes; conditions associated with portal congestion; those in which there are coexisting pathological changes in the anal canal and rectum; and the so-called [illegible] ment is indicated of intestinal anti- the coloproctitis, if present; and suitable surgery of the ano-rectal condition. In the final stages the involved skin in true pruritus usually presents the appearance of an infective dermatitis. As local measures, the authors have obtained better results with dry applications than with solutions or ointments. Other methods to combat infection, relieve the itching, and restore the skin to normal are exposure to *x* rays, ionic medication, vaccines, surgical treatment (the undercutting operation of Ball), and subcutaneous injections. Among the last-named the authors have obtained good results from the use of benacol, a solution consisting of five parts each of ethacaine and benzyl alcohol in ninety parts of rectified sweet almond oil; they report its effects in 200 cases and describe the simple technique. Quadrants are marked out in the perianal region, and the most sensitive one is injected first. The needle is introduced at the outer margin of the pruritic zone, previously prepared with tincture of iodine, and the

solution is injected slowly just beneath the skin, fanwise, as the needle is advanced to and beneath the anal verge; 2 c.cm. is an average amount for each quadrant. Successive quadrants are injected at intervals of two or three days, and the same area may be re-injected in five days, if necessary. To avoid a skin slough it is essential that the injection should be subcutaneous and not intradermal. Pain, ranging from slight to severe, and lasting from one to four or more hours, was reported in 33 cases, but no constitutional reaction was observed.

443. Use of Hypertonic Solutions in Glaucoma.

THE osmotic pressure of the blood can be readily increased by the intravenous injection of crystalloidal or colloidal solutions in the proper concentration, and the effect of such a procedure on the pressure of the cerebro-spinal fluid and the aqueous humour has been known for a number of years. A lowering of intraocular pressure can always be produced by this method, and Lambert and Silbert have reported the effect of intravenous injections of hypertonic solutions on ocular tension in normal subjects. R. K. LAMBERT and J. WOLFF (*Arch. of Ophthalmol.*, August, 1929, p. 198) now record the results of such injections in a small series of nine cases of glaucoma. From 200 to 300 c.cm. of a 5 per cent. solution of sodium chloride was injected intravenously, by gravity, through a small-bore needle; the use of a small needle automatically controls the speed of injection. The total dose of sodium chloride was thus 15 grams or less, which, in the absence of any contraindication, such as nephritis, is said to be entirely non-toxic. Weight-for-weight dextrose is reported as being much less effective than sodium chloride; a 5 per cent. solution of dextrose is isotonic to blood as compared to 0.85 per cent. of sodium chloride. The ideal solution would be a colloidal one, since it would have less tendency to permeate the capillary walls. In each of the cases there was a definite drop in tension varying from 7 to 17 mm. of mercury. The authors admit that the factors controlling the amount of drop cannot be determined from so few cases, but they think it is suggestive that the greatest drop occurred in two cases of acute glaucoma which had the highest initial tension of the series. This method is not put forward as being curative, as it has never produced a permanent drop unaided by other measures, and there is no need for its use in patients who respond well to other forms of treatment. The authors advocate its employment primarily in intractable cases. As an adjuvant to other medications, hypertonic solutions appear to favour their absorption by lowering the tension; in this manner cocaine is more readily absorbed at an operation. Finally, although the value of morphine in certain cases of glaucoma cannot be overestimated, pain and anxiety can be greatly relieved by hypertonic solutions, so that smaller doses of sedatives can be given, to the advantage of the patient.

444. Yatren in Amoebic Dysentery.

ACCORDING to P. H. JONES and R. H. TURNER (*Journ. Amer. Med. Assoc.*, August 24th, 1929, p. 583) the value of therapeutical preparations used in amoebic infestation of the intestine may be judged by the ensuing relief of acute dysenteric symptoms, the prevention of complications and relapses, and the disappearance of cysts from the stools. They agree with Mauson-Bahr and Sayers (*Journal*, 1927, ii, p. 430) that yatren or iodoxyquinoline-sulphonic acid is a valuable aid in the treatment of this disease, and remark that its administration is simple and without danger. It is given in the form of 0.25 gram pills coated with phenyl salicylate; one gram is administered by the mouth three times a day during the first and third weeks, no anti-amoebic treatment being given during the second. The authors state that no restriction of the diet is necessary and the patients need not be kept in bed. Sixty-four patients were thus treated, 42 grams of the drug constituting a course of treatment; subsequent observation of these patients was continued for one to three years. One patient obtained no relief: in another the dysenteric symptoms were controlled, but amoebae continued to appear in the stools after considerable treatment. In the remaining cases there was a prompt and satisfactory response as regards the dysentery, and similarly good results were obtained in children receiving doses proportional to their ages. Rectal ulcers healed in from seven to fourteen days, and no toxic manifestations were noted. Stools of ten patients were examined for cysts some time after the end of treatment, and nine were negative. Thirty-five patients, or 90 per cent. of those with a satisfactory subsequent history, were symptom-free from one to three years after treatment, an average of twenty months. The remaining four patients either had a relapse or showed cystic amoebae in the stool. Further treatment with the same preparation was apparently efficacious.

Anaesthetics.

445. Rectal Anaesthesia in Exophthalmic Goitre.

C. G. HEYD and ADA M. SMITH (*Amer. Journ. of Surg.*, July, 1929, p. 9) describe the technique of the Gwathmey method of rectal anaesthesia, which is said to be eminently suitable in severe goitre cases. The procedure comprises three well-defined periods: the preparation of the patient, the operation, and the post-operative treatment. Prolonged pre-operative treatment is essential in severe types of thyrotoxicosis, especially in the Graves's disease type, and includes the following steps: small, high caloric meals at frequent intervals, together with the administration of fluids by the mouth and rectum; absolute rest and quiet in bed; luminal in 1/4 to 1/2 grain doses, three or four times daily; and Lugol's solution in doses of 1 to 2 c.cm. by the mouth in a full glass of water, half an hour after meals, for three to five days before operation, and by the rectum during the last twenty-four hours before the operation, 2 c.cm. being administered thus in 500 c.cm. of water. An ice-bag is applied during alternate hours to the heart and to the thyroid gland. Transfusion is occasionally, though rarely, indicated; in such a case not more than 500 c.cm. of blood should be given by the direct method. With rectal anaesthesia the patient does not immediately absorb a large amount of ether; absorption takes place gradually, and the etherization is smooth and continuous, since the rate of ether evaporation is constant. It is essential that the amount of ether, as computed by the age, weight, and general condition of the patient, should be given all at one time in order to produce the proper degree of analgesia or anaesthesia. The night before operation pulv. glycyrrhiz. co. (2 to 3 drachms) is administered, and in the morning a soap-suds enema, followed by a colonic irrigation of clear warm water. Two doses of morphine are given three hours and one hour respectively before operation. Two hours before operation a retention enema of chloretone 15 grains, ether 2 drachms, olive oil 1/2 oz., is introduced, and one hour before it the following mixture is placed in the rectum: olive oil 2 oz., ether 4 oz., and paraldehyde 1 drachm. One ounce of this mixture is given for each 20 lb. of body weight. If the patient complains of cramps, burning sensations, and a desire to evacuate the bowels, the flow of the solution is stopped and the tube lowered to allow of the escape of flatus. The tube is clamped and left in the rectum throughout the operation. When this is completed it is removed and the fluid allowed to drain away. After the operation morphine should be given every four to six hours for pain and restlessness; water by the mouth as soon as consciousness returns; and proctoclysis, every eight hours with 500 c.cm. of water containing 50 grams of glucose and 2 c.cm. of Lugol's solution. Digitalis should be administered if indicated, and quinidine, 3 grains every four to six hours, if fibrillation is present. The patient should be kept in the sitting or Fowler position. Many advantages are claimed for this method, among which are its safety and lessened mortality.

446. Influence of Anaesthetics on the Blood Volume.

H. REISSINGER and H. SCHNEIDER (*Deut. Zeit. f. Chir.*, July, 1929, p. 303), using the carbonic oxide method, have studied the influence of surgical operations on the volume of the circulating blood. In general narcosis there is a definite diminution of the blood volume, which is determined by the duration of the anaesthesia and by the drug and method employed. Chloroform and avertin cause a more marked lowering of the blood volume than ether. With local anaesthesia, in contrast with general narcosis, the diminution of the blood volume is not so marked, and the volume may even be increased; this increase is attributed to the action of absorbed adrenaline on the small peripheral arteries and the persistence of the normal muscle tone during the anaesthesia. The nature of the operation is also a factor, abdominal operations being associated especially with marked diminution of the blood volume, such as occurs in traumatic shock, or after experimental manipulation in animals by tearing and pulling on the abdominal organs. The lowering of the blood volume expresses a commencing collapse of the circulation; this can be met by the administration of adrenaline and strychnine, which act by increasing the volume of the blood.

447. An Anaesthetic of Diminished Toxicity.

IN a preliminary report G. H. W. LUCAS and V. E. HENDERSON (*Canadian Med. Assoc. Journ.*, August, 1929, p. 173) record a series of animal experiments which demonstrate the anaesthetic properties of a gas named cyclopropane, which is prepared from trimethylene bromide. It has a sweetish smell, like a mixture of chloroform and ethylene; it is heavier than air and is explosive in 5 per cent. and upwards

of oxygen, but it does not explode in mixtures weaker than 10 per cent. Cyclopropane appears to be an anaesthetic of high potency, 10 to 12 per cent. producing deep surgical anaesthesia in the test animals. Its toxic properties seem to be but slight, and toxic features do not appear rapidly except in concentrations higher than those named, the fatal concentration ranging between 27 and 30 per cent. In high percentages of the gas there is a decrease in respiratory depth and frequently in rate, and in some cases a fall in blood pressure. Respiration fails before the heart and circulation, and the heart appears to be but little affected. In no case did the heart not show a high degree of efficiency. The fall in blood pressure seems to be of vasomotor origin, and metabolic effects are slight or absent. Recovery is prompt and with little after-effects; it is very rapid in the case of doses toxic to respiration, but if the toxicity has shown itself in a fall of blood pressure recovery is not so brisk.

Obstetrics and Gynaecology.

448. Uterine Displacements and their Treatment.

IN a discussion of movable backward displacements, P. WERNER (*Wien. klin. Woch.*, August 15th, 1929, p. 1084) mentions that the congenital variety is usually a retroflexion only; the acquired form comprises a retroversion and flexion, being often part of a general visceroptosis and the first stage of a prolapse. The symptoms are backache, a bearing-down feeling, sterility, disturbances of menstruation, and nervousness. Werner finds it hard to be certain to what extent the displacement is responsible for these, and treatment by pessary will show whether or not reposition of the uterus effects a cure. Treatment is usually satisfactory when the main complaint is either sterility, visceroptosis, or menorrhagia. If conception occurs the uterus becomes too large for the pelvis about the end of the third month, and three solutions are possible: it may right itself, abortion may come on, or an incarceration of the gravid uterus may ensue, with its serious results. Before treating a retroversion its mobility must be established beyond doubt; reposition may be attempted manually, preferably not with the sound, and better still with the vulsellum. A speculum is introduced and the anterior lip of the cervix is grasped; traction is made, first downwards in the axis of the vagina, and then the handle is raised, leaving the point unmoved. Finally, the cervix is pushed back as far as possible into the posterior fornix, thereby anteverting the uterus. Any uterus which cannot be replaced thus must be considered fixed. The reposition of the gravid uterus must be done with the utmost care to avoid abortion. The vulsellum method is considered inadvisable, but the knee-elbow position is worth trying, since the weight of the uterus will bring it forward. If this method fails a rubber balloon may be inserted into the vagina and filled slowly with about 20 oz. of mercury, the patient being in the lithotomy position. The mercury fills up the posterior fornix and the hollow of the sacrum, thereby pushing the uterus forwards; this is held to be the best method in pregnancy. The non-gravid uterus after reposition must be kept anteverted, either by pessary or operation. Pessary treatment, in spite of its disadvantages, may effect a cure by taking the strain off the uterine supports and allowing them to regain tone. When pessary treatment is impossible an operation must be performed. The uterus should never be fixed to any one point in view of possible pregnancy, but anteverted by means of the round ligaments; the method of Wertheim is said to be the operation of choice.

449. Section of the Utero-sacral Ligaments.

H. MOLIN and F. CONDAMIN (*Gynécol. et Obstet.*, July, 1929, p. 100) describe the utero-sacral ligaments as being essentially formed of two parts: a fibro-elastic tissue, which duplicates the peritoneal serous layer, and a nerve bundle, which arises from the hypogastric plexus and is more deeply situated. These ligaments represent the true nerve pedicle of the uterus, and they have a mechanical and nervous action. Thus their section produces a double effect—namely, a mechanical one which frees the uterus from posterior retractions, and a nervous one which interrupts the passage of painful nerve impulses. Inflammation of the utero-sacral ligaments leads in the acute stage to painful tension, and in the chronic stage to more or less retraction; it can arise from two processes, which cause practically identical lesions. The infection may be through the lymphatics or by continuity from the parametric cellular tissue, giving rise to the posterior parametritis of Schultze, or it may be propagated downward from a peritoneal focus and originate the douglasitis of Condamin. The present authors claim that uterine retroversions merit greater attention than is usually given to them, and distinguish two opposite types of these conditions: those due to ligamentary relaxation, and those due to ligamentary retraction, particularly of the utero-sacral ligaments. Treatment of the retroversion alone is said to be useless in chronic parametritis or douglasitis; in these conditions section of the ligaments has given excellent results by maintaining the uterus in its normal position and abolishing the lumbo-sacral pains. In performing the operation the ligaments should be cut close to their isthmic insertion. Fourteen cases are reported in which this procedure was adopted with great benefit. Indications for its use are as follows: as a complement to ligamentopexies and hysteropexies for retroversions due to retraction of these ligaments; as a complement to conservative measures for chronic conditions of the adnexa: in retroversions which cannot safely be treated by other measures; and in posterior parametritis or douglasitis after complete regression of the causal lesions.

450. Leucorrhoea due to Trichomonas vaginalis.

C. H. DAVIS (*Amer. Journ. Obstet. and Gynecol.*, August, 1929, p. 196) states that in a series of about 1,000 gynaecological and obstetrical patients 33 per cent. suffered from leucorrhoea. The causes and associated conditions of this discharge he classifies under four headings: (1) parasitic and infective: (2) local; (3) constitutional; and (4) circulatory. In the first group he includes the organisms of specific disease, pyogenic and protozoal infection among others, and states that these may often be associated with any of the inflammatory or neoplastic conditions of the genital tract found in the second group. At the same time a predisposing factor may be present in the form of anaemia, or of some disease of the circulatory system, producing a vascular stasis with pelvic congestion. Davis advises that smears should be diluted with normal saline, when, if examined fresh, the *Trichomonas vaginalis* will be demonstrated quite frequently. To this organism he attributes, in great measure, vaginal leucorrhoea. Before treatment is begun he advises a thorough and systematic examination of the patient as well as the local investigation. In acute cases treatment should consist of non-irritating irrigation by a nurse, cleansing of the external genitalia by liquid soap and water, sitz baths, and confinement to bed. Once the acute stage has passed the vagina should be dried and painted with 5 per cent. mercurochrome or the compound tincture of benzoin. Medicated tampons he considers of doubtful value. In chronic cases, where the cause is usually an endocervicitis, he advocates treatment by the electro-cautery or excision of diseased tissue by a Sturmdorf or Schroeder operation. When the vaginitis is due to the *Trichomonas vaginalis* the cervix should be cauterized, and, in addition, the vagina should be treated four times weekly, or even daily, by swabbing with 1 per cent. lysol solution and drying, painting with 5 per cent. mercurochrome, and packing with 5 per cent. ichthyol in glycerin.

451. Blood Transfusion in Gynaecology.

B. S. TEN BERGE (*Nederl. Tijdschr. v. Geneesk.*, July 20th, 1929, p. 3344) records his observations in 71 cases treated by blood transfusion in the Coolsingel Hospital at Rotterdam. The procedure was at first used only for women who had had profuse haemorrhage, but it was afterwards employed in cases of cancer of the cervix or uterine fibroids to diminish the dangers of the operation. Transfusion was also employed in severe infective processes following normal delivery or abortion, in violent haemorrhage associated with retained placenta in which curetting or manual removal was inadvisable, in severe shock following operation, and in profuse haemorrhage following normal delivery or abortion. The sodium citrate method was first used, but as this was always followed by a rise of temperature the direct method was substituted, in which coagulation of the blood is prevented by smearing with paraffin the walls of the vessel into which the blood is received. The blood group is determined by *Moss's method*. Apart from a slight rise of temperature and an urticarial rash in a few cases, no bad effects resulted from the direct method.

452. Racial Influences and Obstetrics.

H. RUMMEL (*Zentralbl. f. Gynäk.*, August 10th, 1929, p. 2006) describes some of the anatomical and other peculiarities which are met with among the women of Southern China; he regards them as racial and constitutional. The prevailing type of pelvis in Canton has a transversely oval entrance, with an outside measurement usually 2 to 3 cm. less than that of the European pelvis; there is a very marked frequency of round pelves; these shapes of pelvis are possibly the effect of the squatting habit. The presence of cystic ovarian tumours is also said to be a racial characteristic of these women. The remarkable rareness of miscarriages and septic abortions may be related to the absence of functional disturbances, such as vaginismus and dyspareunia; the ancient Chinese custom of honouring and respecting the

mother of a family encourages a fondness for propagating children. In South China stone in the bladder is very common, especially among the peasant communities; cases of appendicitis and cholelithiasis are remarkably rare—attributable, perhaps, to the rice diet and lower cholesterin intake. Anal fistula and abdominal tuberculosis are surprisingly common, and are often accompanied by abscess of the symphysis. Amenorrhœa and sterility are due to chronic malaria, ankylostomiasis, and beri-beri; they may appear as the early signs of leprosy, or follow typhoid fever and pulmonary tuberculosis. In the wealthy, sunny districts of Southern China rickets and osteomalacia are almost unknown, but they occur abundantly in some of the north-west provinces, where a poor, ill-nourished population live through the long winters in miserable dwellings.

Pathology.

453. Asthenia following Suprarenal Destruction.

J.-E. ABELOUS and H. LASSALLE (*C. R. Soc. de Biologie*, August 13th, 1929, p. 938) state that it is generally agreed that asthenia is the cardinal symptom of suprarenal insufficiency. From their researches on the functions of these glands Abelous and Langlois attributed the asthenia to an "autocurarization" due to an accumulation in the organism of toxic substances normally neutralized or destroyed by the suprarenals. This theory has been disputed by many investigators. In some adrenalectomized animals, on the approach of or soon after death, excitation of a motor nerve causes no muscular contractions, while in others it does. These contradictory results have led many physiologists to deny the analogy between the motive impotence noted and the paralysis caused by curare. Lapicque has shown that the paralysis following the administration of curare is due to a considerable difference of chronaxy between the nerve and muscle, the chronaxy of the latter being much greater than that of the former. The present workers state that this heterochronism is the rule after destruction of the suprarenals, the discrepancy increasing and becoming very great just before death. Experiments on frogs and toads have proved that total destruction of the glands is followed fatally, after a more or less brief interval, by a profound asthenia, which is accentuated till death supervenes. This asthenia is caused by poisons no longer neutralized by the suprarenals, and these poisons have an action similar to that of curare, as is evidenced by the heterochronism demonstrated between the nerve and muscle.

454. An Alkalization Test of Renal Function.

As a result of tests extending over two and a half years and applied to 128 patients M. ROSENBURG and A. HELLFORS (*Deut. med. Woch.*, July 19th, 1929, p. 1212) recommend an alkalization method of testing renal function. The results were found to correspond with those obtained from the water and concentration tests, and the procedure was also found to be applicable to cases with oedema in which the other two gave inaccurate results. A further advantage of the method was that it took less time than the others, and gave evidence of slight renal deficiency. The test is carried out as follows. The fasting patient receives in the morning 20 grams of sodium bicarbonate in 400 c.cm. of water, and the *p*H of the urine is estimated at half-hourly intervals afterwards by the Michaeli method. With normal kidneys this value rises to at least 8.0; if the renal function is impaired the rise is proportionately diminished. This result depends on two important factors: (1) disturbance of the acid-alkali exchange between the tissues and blood; and (2) inadequate excretion of alkaline constituents by damaged kidneys. The fact that increase in the blood alkali reserve and alteration in the urinary *p*H do not run a parallel course after the administration of alkali indicates the importance of both factors; it has also been found that the blood alkali reserve observed is of little value as a guide to renal anomalies in gastric secretion was not confirmed in a number of control cases.

455. The Reticulocyte Count.

A. FRIEDLANDER and CHARLOTTE WIEDEMER (*Arch. Int. Med.*, August, 1929, p. 209) have been investigating the reticulocyte count in normal and abnormal conditions; they describe a simple method of staining the blood cells with brilliant cresyl blue which enables the count to be made more rapidly and accurately. The authors believe that the reticulocyte percentages often given are much too high; such percentages as 1 and 1.5 of the red cells are excessive for normal persons, a more accurate range being from 0.03 to 0.2 per cent., so that in a healthy adult these cells are not present in higher numbers than 10,000 per c.mm. A seasonal variation in the count is said to be usual, there being a definite increase during the spring as compared with the winter months; this is attributed to stimulation by the ultra-violet rays in sunshine, a suggestion which receives support from the fact that an increase in reticulocytes occurs after heliotherapy by both natural and artificial rays. Increases were noted in the newborn infant and during pregnancy. No connexion appears to exist between the white cell and the reticulocyte count, little variation of the latter from the normal having been detected by the authors in acute and chronic infections and diseases, unless there was a complicating anaemia. Counts were high in workers in lead factories, though they showed no clinical symptoms of poisoning, and a similar increase was noted in cases of corrosive mercuric chloride poisoning. The authors state that in cases of haemorrhage the maximum reticulocyte count is normally reached about five days after the bleeding has ceased; with the subsequent rise in the red cell count and its approach to normal the reticulocyte count drops, and may thus afford a prognostic index as to whether blood regeneration will proceed normally after haemorrhage has stopped. The value of the reticulocyte count in this connexion in pernicious anaemia is already accepted; in patients under liver extract treatment the reticulocyte count drops to normal as the red cell count reaches its maximum.

456. Differentiation of Haemolytic Streptococci.

R. C. AVERY (*Journ. Exper. Med.*, October 1st, 1929, p. 463) has examined 138 strains of haemolytic streptococci, collected from human and bovine sources, from fresh and pasteurized milk, and from cheese. Studying their growth in glucose broth, he finds that two groups can be distinguished according to their degree of acid production; 95 strains, all except 4 of which were of human origin, produced a final acidity of *p*H 5.3 to 5.0; the remaining 43 strains, none of which was of human origin, produced a final acidity of *p*H 4.5 to 4.0. The strains were further tested as regards their capacity to reduce methylene blue. For this purpose tubes of milk containing a 1 in 5,000 solution of methylene blue were inoculated with 0.1 c.cm. of a twenty-four-hour broth culture of the strain to be tested, and incubated for seven days. Only one of the 95 low-acid-producing strains reduced methylene blue; of the 43 high-acid-producing strains, 24 reduced methylene blue, and 19 failed to do so. Of the 24 strains showing reduction, 21 were from various kinds of cheese. The author concludes that haemolytic streptococci may be divided on these two tests into three groups: (1) human parasitic strains, having a final *p*H of 5.2 to 5.0, and failing to reduce a 1 in 5,000 solution of methylene blue in milk; (2) bovine strains, parasitic in the udder, having a final *p*H of 4.5 to 4.2, and failing to reduce methylene blue in milk; and (3) saprophytic strains, found in milk and cheese, having a final *p*H of 4.5 to 4.2, and reducing methylene blue in milk. It was found that methylene blue was bactericidal for strains of haemolytic streptococci that failed to reduce it, but that it was neither bactericidal nor bacteriostatic for those which reduced it.

457. Production of Rachitic Scoliosis by Strontium Administration.

S. MARCONI (*La Chir. degli Organi di Movimento*, July, 1929, p. 585) has recently confirmed the work of Cagnetto, who by adding strontium to the daily diet produced an experimental scoliosis in young chickens. There was neither reduction nor suppression of calcium. Marconi's object was to study the deformity obtained and the dynamic principles governing it. The first experiments were made with guinea-pigs, but the results obtained were not sufficiently good. Chickens were found to yield better results, and to be more comparable with the human. The chickens were given an emulsion of a strontium salt, the proportion being 0.2 gram for 100 grams of body weight. Care was used to exclude the presence of barium. The increase of dosage was regulated by the body weight and also by the tolerance of the animal. A typical scoliosis in no way distinguishable from a rachitic scoliosis was produced in one case before the animal died on the hundred and twenty-second day. From direct study, photographs, and skiagraphs it appeared evident that the deformity of the vertebral column followed constant rules, analogous to those observed in the human subject. In addition to the principal curve there was a compensatory one, associated with torsion of the column with a costal hump. The usual secondary deformities of ribs, sternum, shoulder, and pelvic girdles were present. Examination of the vertebral deformity showed that at the apex of the principal curve there was a cuneiform vertebra, and in the compensatory curve the characteristic oblique or rhomboidal vertebra.

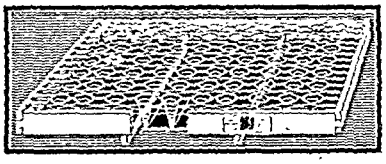
OF DEFINITE VALUE IN THE PROMOTION OF SLEEP

AS SUPPLIED TO H.M. THE KING

There is one physic which never fails of its purpose—sleep. A Staples Mattress will not ensure it, but is of definite value in promoting it. The reason is simple—the lithe steel springs *afford equal support to all parts of the body*—thus the muscles are fully relaxed and the nerves automatically follow suit—sleep is naturally *induced* with the Spine Straight and the internal and digestive organs undistorted.

BY APPOINTMENT
Wire Mattress and Bedstead Manufacturers to H.M. THE KING

Sold by ALL Furnishers 3ft. 99/-, 4ft. 6ins. 118/6



STAPLES MATTRESS

"The finest mattress made"
Regd.

A visit to our works showroom at Staples Corner, Crick'lewood, is well worth while. The "Commonsense Health" Mattress Booklet and new 1929 catalogue of Staples Bedstead Designs, are sent post free on application to Dept. 4.

The **SPECIFIC OVARIAN HORMONE**
which normally controls and activates the menstrual cycle

SISTOMENSIN
standardised physiologically

dysmenorrhœa, menorrhagia, hæmorrhages of puberty and menopause, hypoplasia of the uterus, disturbances subsequent to menopause or oöphorectomy.

Tablets Ampoules

PROKLIMAN
(Sistomensin Compound)

Association of ovarian hormone with therapeutic agents for the prompt relief of the most pronounced troubles of menopause: cardiovascular and nervous troubles, hot flushes, headache, etc.

Tablets

Hydrosoluble Ovarian Substance

AGOMENSIN

causes hyperæmia of the female genital organs. Stimulates the function of the genital glands and menstruation.

Functional amenorrhœa, oligomenorrhœa, sterility, vomiting during pregnancy, etc.

Tablets Ampoules

Clinical Reports on request

THE POWER OF "VITA" GLASS IS PERMANENT

It allows Constant Passage to the Ultra-violet Rays year in and year out

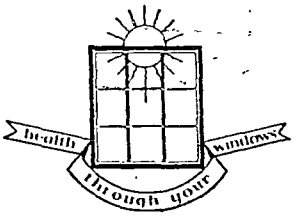
The power of "Vita" Glass to transmit the ultra-violet rays is stabilised permanently within a few months after it is fitted. Thereafter it may be accepted as a perpetual inlet for the health rays in daylight.

This fact (and ample proof of it is readily available), will serve to reassure medical practitioners who may have hesitated to recommend "Vita" Glass for the windows of their patients.

Now that an average-sized bay window in a modern house can be "Vita" Glazed for 38/- plus the cost of fixing, it has become quite a practicable course for private persons even of quite moderate means.

Further information about "Vita" Glass with the names of some of the 180 hospitals and 100 schools with "Vita" Glass windows will be forwarded to any interested medical man. Write to the "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.



"Vita" is the registered Trade Mark of Pilkington Brothers Limited St. Helens.

Telephone No.: Gerrard 3185.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE. *Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.*

MEDICAL REPORTS. *Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.*

HOME TESTS ARRANGED FOR DOCTORS AND PATIENTS. *Medical prescriptions made up to the minutest detail.*

Salt and Son Ltd.

Five Essentials of an Artificial Leg

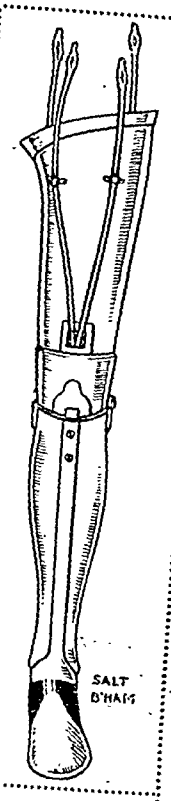
SALT'S LIGHT METAL LIMB FOR ABOVE KNEE AMPUTATION.

This illustrates one of our many artificial legs. When fitted by us it possesses the FIVE essentials mentioned.

Made of duralumin with wooden foot, it weighs only 3¾ lb. for an adult male patient.

We manufacture wooden, leather, and metal limbs for all types of amputation, and can send expert fitters to any part of the country.

Illustrated lists sent on request.



Comfort is naturally the first consideration.

Lightness reduces the physical strain to a minimum.

Action governs rapidity of movement and natural gait.

Appearance is maintained when made to match the fellow limb.

Simplicity in construction lessens cost and maintenance.

A Wise Choice
—a GAMAGE LIVERY

The Chauffeur pictured here. How smart and dignified he looks. His overcoat is an outstanding example of GAMAGES EXPERT LIVERY TAILORING. Your Chauffeur, too, will look well in a GAMAGE LIVERY—not only when it is new, but throughout a very long period of hard wear. And the wisdom of choosing a GAMAGE LIVERY is further exemplified by the moderate prices. For instance, 75/-, the Overcoat, ready-to-wear, or made to measure.

The GAMAGE "CAVENDISH" OVERCOAT

Made from hard-wearing Blue Melton Cloths and lined Tweed throughout. Overcoats are made in two styles—(1) as illustrated: (2) button to neck. Ready for service in all fittings. 95/-, 115/6, **75/-**

Full range of patterns and self measure chart on request.

Put this heater in your CONSULTING ROOMS

for cheerful, comforting warmth—*when needed*. The "FLORENCE" is far ahead of other oil stoves. It has two patent wickless burners which unite the vaporised paraffin with air and give perfect combustion—an immense volume of heat for the small amount of oil used—without smell or smoke. And each burner is separately controlled—a turn gives the desired heat. All working parts are built into a handsome cabinet finished in grained mahogany porcelain enamel.

JAEGER

Pure Wool

K K UNDERWEAR.

Even Medical Men do get Colds.

That is why Jaeger, with its special health-preserving properties, appeals to the Profession. There are many excellent varieties of Jaeger Underwear, but KK is particularly mentioned as being most suitable. The weight, for instance, is medium; it has been carefully chosen and does not vary, which is a vital consideration; while the wool, which is wonderfully soft and gives real comfort, is also hard-wearing.

"Tailoring to Tradition"

By Appointment to H.M. the King and to H.R.H. the Prince of Wales.

The S.B. "SANDHURST" as illustrated is tailored in all-wool weatherproof Aquascutum cloth; also in exclusive Tweeds and Covert Coatings, from 6 guineas, ready to wear or to order. Greatcoats in "Eiderscutum," Lambswool Fleeces, and Camel Hair from 9 guineas. "Field" Coats 3½ to 5 gns.

An Appreciation—

"I may say the coat is everything that could be expected, and here, in the North of Ireland where we have generally cold winds and rain, it really 'keeps the life in one.' I could not desire a better garment, and I question if it would be possible to obtain any for all-round purposes such as my Aquascutum. It has been admired everywhere I go, and I am continually going from place to place in discharge of my duties. . . . ."

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra violet Apparatus and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 55, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

S. FORREST COWELL,
November 16th, 1929. Secretary.

Barry Urban District Council.

SURGICAL HOSPITAL.

HOUSE SURGEON (Male).

Applications are invited for the above appointment. Candidates must be duly qualified and registered. Salary £200 per annum, with board and lodging.

Preference will be given to a candidate with previous experience, especially in the administration of anæsthetics.

The successful candidate must devote the whole of his time to the duties of his office and to assist the Medical Staff, and act under the supervision of the Medical Superintendent, who is also Medical Officer of Health and School Medical Officer.

The appointment will be for a period of six months, to be renewed, if thought fit, for another period of six months, but not for any subsequent period.

The successful candidate will be required to commence duties January 1st, 1930.

Applications, stating age, qualifications, positions held, with copies of three recent testimonials, to be sent to Dr. P. W. KENT, Medical Superintendent, Public Health Office, Barry.

(Signed) T. B. TORDOFF,
November 2nd, 1929. Clerk.

City of Birmingham.

MATERNITY AND CHILD WELFARE DEPT.

RESIDENT MEDICAL OFFICER.

A Resident Medical Officer is required on January 1st next, for a period of six months, for the CITY BABIES' HOSPITAL (50 beds). Salary at the rate of £150 per annum, with board and laundry. Previous experience in a Children's Hospital desirable. Apply, giving all particulars of qualifications, age, and experience, to the Medical Officer of Health, the Council House, Birmingham, on or before Thursday, November 28th.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of a Male Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the medical inspection of school children, maternity and child welfare, and the treatment of tuberculosis and venereal diseases. The officer appointed will be required to undertake such other public health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, *inter alia*, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, 5, Grove Crescent, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any inquiries relating to the appointment should be addressed.

Last day for receipt of applications, Saturday, November 30th. Canvassing, directly or indirectly, will disqualify.

County Hall, DUDLEY AUKLAND,
Kingston-upon-Thames. Clerk of the
November 8th, 1929. County Council.

Parish of Ipswich.

ASSISTANT RESIDENT MEDICAL OFFICER (Female).

The Guardians of the Poor of the Parish of Ipswich [illegible]ified
Medical [illegible]stant
Resident IN-
FIRMARY ST.
JOHN'S £250
per annum, with board and residence. The appointment is subject to termination by six weeks' notice on either side.

The accommodation of the Heathfields Infirmary is for about 250 patients, and of Heathfield House about 230 inmates. The number of children in St. John's Home is about 150.

The candidate appointed will be required to act generally under the direction of the Visiting Medical Officer, and to give lectures to the Probationer Nurses.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three testimonials, to be sent to me endorsed "Assistant Resident Medical Officer," not later than Monday, November 25th.

L. W. GREENHALGH,
Guardians' Offices, Clerk to the
19, Tower St., Ipswich. Guardians.
November 5th, 1929.

The King Edward VII Welsh NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered Medical Practitioners for the post of AREA ASSISTANT TUBERCULOSIS PHYSICIAN. Salary £600 per annum, together with travelling and subsistence allowances when absent from base. Preferably candidates should have had at least six months' special training in Tuberculosis, with eighteen months' experience in general clinical work, of which six months should have been spent in a Hospital not confined to the treatment of Tuberculosis.

Applications, stating full qualifications and previous experience, together with copies of three recent testimonials, should reach the undersigned not later than November 30th.

Memorial Offices, D. A. POWELL,
Westgate St., Principal Medical
Cardiff. Officer.

The Royal College of Saint KATHARINE, Poplar, E.14.

MATERNITY AND CHILD WELFARE CENTRE.

Applications are invited for the post of ASSISTANT MEDICAL OFFICER to one of the Infant Clinics.

Candidates must be fully qualified and registered and should state in their application what previous experience they have had in the diseases of children and in Infant Welfare work.

Salary £1 11s. 6d. per session.

Applications, with copies of three recent testimonials, should be submitted not later than November 25th to the Principal, The Royal College of St. Katharine, Brunswick Road, Poplar, E.14.

Birmingham Union. DUDLEY ROAD HOSPITAL.

SURGEON.

Applications are invited from fully qualified registered Medical Practitioners for the above appointment.

The Hospital accommodation is fixed by the Guardians at 926, divided into Medical, Surgical, Children's, Infectious, Gynæcological and Obstetrical Sections. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical, Massage, Sunlight, and Dental Departments. Approximately 6,000 operations are performed annually.

Candidates for the appointment must have had good Surgical experience, and be Fellows of the Royal College of Surgeons (England).

The scale of salary will be £700, rising by annual increments of £50 to a maximum of £1,000 per annum, and the salary of the successful candidate will be fixed within the scale according to experience and qualifications.

Furnished quarters, rations, laundry, and attendance will be provided by the Guardians. Alternatively, a cash allowance will be paid if the officer appointed is non-resident. A deduction of 2 per cent. will be made from the salary and value of emoluments under the provision of the Poor Law Officers Superannuation Act, 1896.

Further particulars of the appointment may be obtained from the Chief Medical Officer, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than 11 a.m. on Monday, November 25th.

Union Offices, C. P. BEECH,
Birmingham. Clerk to the
November 4th, 1929. Guardians.

Worcestershire County Council.

ASSISTANT COUNTY MEDICAL OFFICER.

The above-mentioned Council are about to appoint an Assistant County Medical Officer, and applications are now invited for this post.

Applicants must be registered Medical Practitioners between the ages of 25 and 45.

The duties will include attendance at Infant Welfare and Ante-Natal Centres, and the medical examination of elementary and secondary school children. Special Post-Graduate experience in Children's Diseases is especially desirable.

The officer who is appointed will work under the supervision of the County Medical Officer, and will be required to reside in the district assigned to him or her by the County Council, and to devote the whole of his or her time to the work.

The salary will be £600 per annum, with an allowance of £140 per annum for use of own motor car, or a car will be supplied for County work.

The engagement will be subject to three months' notice on either side.

Applications (on forms to be obtained from the County Medical Officer, 29, Foregate St., Worcester), accompanied by not more than three recent testimonials, must be received by 12 noon on Thursday, November 28th, addressed to the County Medical Officer, 29, Foregate Street, Worcester.

Canvassing disqualifies, and neither the names of the Members of the County Council nor of the Committee will be supplied.

(Signed) C. H. BIRD,
Shirehall, Clerk of the County
Worcester. Council.
November 5th, 1929. (V.135.)

Rochford Union.

JUNIOR ASSISTANT MEDICAL OFFICER (RESIDENT).

The Guardians of the above-named Union invite applications for the appointment of Junior Assistant Medical Officer at the Poor Law Hospital, Rochford.

The appointment will be renewable at the expiration of six months in the first instance, and thereafter annually at the discretion of the Guardians.

Salary £225 per annum, rising after six months' satisfactory service to £275 per annum, with furnished apartments, rations, laundry, and attendance. The emoluments, for the purposes of the Poor Law Officers Superannuation Act, are assessed at £100 per annum.

Applicants must be fully qualified, and preference will be given to candidates who have held appointments as House Physicians or House Surgeons in Public General Hospitals.

Applications, on forms which can be obtained from me, must reach me not later than Monday, December 2nd.

By Order,
W. HARDING ROBERTS,
Clerk.
27, Victoria Avenue,
Southend-on-Sea. November, 1929.

SURGEON TO OUT-PATIENTS.

A Meeting of the Committee of Election will be held on December 9th, at 11.45 a.m., for the purpose of electing a Surgeon to Out-patients.

Applications are invited for the post.

It is required that candidates shall be Fellows of the Royal College of Surgeons of England, or undertake to become so within twelve months of their election.

The successful candidate will be appointed for a term of three years, and will be eligible for re-election.

After six years his honorarium (£40 per annum) will cease, and he will be called Surgeon to the Hospital.

Particulars as to the duties can be obtained on application to the undersigned, to whom applications, accompanied by Diplomas and certificate of registration, should be sent by November 30th.

HAROLD F. SHRIMPTON, House Governor.

November 11th, 1929.

The Institute of Ray Therapy, 152-154, Camden Road, N.W.5.

A Ray Therapy (Artificial Sunlight) Clinic will be opened on January 4th, 1930, at the above address for purposes of Treatment, Research, and Training of Nurses and Practitioners.

A JUNIOR MEDICAL OFFICER is required to assist in treatment from 2 p.m. to 9 p.m. daily.

An honorarium at the rate of £150 per annum is offered, together with board, residence, and laundry.

The appointment is for six months, and there will be opportunity for Post-Graduate work and study.

Applicants must have held a resident appointment at a General Hospital, but experience in ray therapy is not essential.

Applications, together with copies of three testimonials, should be sent not later than Dec. 14th to the MEDICAL SUPERINTENDENT, c/o No. 7314, B.M.A. House, Tavistock Square, W.C.1.

East London Hospital for CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.1.

The Board of Management invite applications for the post of SURGEON to the Nose, Throat, and Ear Department, to see Out-patients one day a week.

By Section 6, subsections 19 and 20 of the Constitutions of the Hospital, every Surgeon shall be a Fellow of the Royal College of Surgeons of England.

Applications, with copies of testimonials, should be addressed to the undersigned and delivered to the Hospital on or before Saturday, November 30th.

By Order of the Board of Management,

November 12th, 1929.

House Surgeon (male) wanted

for HUNTINGDON COUNTY HOSPITAL, November 30th. Salary £125 per annum, and laundry.—Apply Dr. Gwyn, County Hospital, Huntingdon.

Nottinghamshire County Council

SECOND ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Practitioners for the appointment of Second Assistant County Medical Officer at a salary of £700 per annum, rising, subject to satisfactory service, by annual increments of £25 to £750, together with travelling expenses in accordance with the County Council's Scale.

Candidates must possess a Diploma in Public Health, and have held one or more resident Hospital or Institutional appointments. Preference will be given to candidates who have had administrative experience in a Public Health Department, preferably in a County.

The person appointed will be required to work under the supervision and control of the County Medical Officer, to devote his whole time to the duties of his office, and to carry out such duties as may be assigned to him by the County Medical Officer. He will be required to reside in such part of the County as may be approved.

The selected candidate will be required to pass a medical examination.

The appointment will be terminable by three months' notice, in writing, on either side.

Applications, on forms which may be obtained from the undersigned, with copies of not more than three recent testimonials, should be forwarded to the County Medical Officer, Shire Hall, Nottingham, not later than Wednesday, November 27th.

Shire Hall, Nottingham. November, 1929.

K. TWEEDALE MEABY, Clerk of the County Council.

Nottinghamshire County Council

EDUCATION COMMITTEE.

SENIOR DENTAL OFFICER (Male).

Applications are invited for the post of Senior Dental Officer at a salary of £610 per annum, rising, subject to satisfactory service, by annual increments of £20 to £650, with travelling expenses in accordance with the County Council's Scale. Candidates must be fully qualified and registered Dental Surgeons, and must have had experience of Dental work under an Education Authority. Administrative experience will be deemed an additional qualification.

The successful candidate will be required to work under the supervision and control of the County Medical Officer, and to reside in such part of the County as may be approved.

For such part of his time as is not required for administrative work he will be required to carry out clinical duties as may be determined.

Private practice will not be allowed.

The selected candidate will be required to pass a medical examination, and the appointment will be terminable by three months' notice, in writing, on either side.

Applications, on forms which may be obtained from the undersigned, with copies of not more than three recent testimonials, should be forwarded to the County Medical Officer, Shire Hall, Nottingham, not later than Wednesday, November 27th.

Shire Hall, Nottingham. November, 1929.

Applications, stating age, and accompanied by copies of testimonials, to be sent to the undersigned not later than first post on Tuesday, November 26th.

J. ROWSE MITCHELL, Secretary.

The Prince of Wales's General Hospital, Tottenham, N.15.

Appointments of HONORARY CLINICAL ASSISTANTS to the various Departments of the Hospital (Surgical, Medical, Gynæcological, Ear, Nose, and Throat, Eye, Skin, X-ray and Electrical) for the ensuing year will be made in December.

Applications for appointment to any of these posts should be sent to me on before Monday, December 2nd next.

FREDK. W. DREWETT, Director

November 11th, 1929.

Resident Medical Officer required

for LEEDS JEWISH HERZL-MOSER HOSPITAL, commencing duties December 1st. Salary £100 per annum, full board. Ample time for post-graduate work.—Apply, Secretary, Herzl-Moser Hospital, Leopold Street, Leeds.

Parish of Whittlesey.

DISTRICT MEDICAL OFFICER, PUBLIC VACCINATOR, AND MEDICAL OFFICER OF THE WORKHOUSE WANTED.

The Guardians of the above Parish invite applications from duly qualified Medical Practitioners for the above appointments.

The district comprises the Southern portion of the Parish, approximate acreage 13,600, and containing a population of about 4,207.

The salary of District Medical Officer will be £50 per annum, with the usual extra medical fees for midwifery and surgical cases as prescribed by the Ministry of Health.

The fees for Vaccination are those prescribed by the Vaccination Orders.

The salary of Medical Officer of the Workhouse will be £40 per annum.

The gentleman appointed will be required to reside within the district, and he must be prepared to enter upon his duties on January 1st, 1930.

Applications, stating qualifications, and enclosing copies of three testimonials of recent date, endorsed "Application for Medical Officer," must reach me on or before November 30th.

By Order,
JOHN W. BOWKER, Clerk.

Whittlesey, Near Peterborough. November, 1929.

Perthshire Joint Medical Service

SCHEME.

A FIRST ASSISTANT MEDICAL OFFICER (male) is required under the above Scheme in the County of Perth.

The possession of a D.P.H. and Hospital experience are essential. Experience in any branch of Public Health, including Tuberculosis and School Medical work, will be added recommendations. Salary £600 per annum, rising by annual increments of £25 to £750, subject to satisfactory service.

Forms of application may be obtained from the undersigned, with whom completed applications, accompanied by copies of three recent testimonials, should be lodged not later than December 6th.

County Buildings, Perth. Dr. D. J. McLEISH, Medical Officer of Health.

National Hospital, Queen Sq., W.C.1.

Applications are invited for the post of RESIDENT MEDICAL OFFICER, which will be vacant at the end of the year, and should be sent to the undersigned, accompanied by copies of three testimonials, not later than Monday, November 25th. The salary is £200 per annum, with board and lodging. Applicants should state if they are willing to accept a post of House Physician (salary £150).

GODFREY H. HAMILTON, Secretary.

Rochdale Infirmary and Dispensary. (110 Beds.)

Wanted, JUNIOR HOUSE SURGEON (male). Salary £175 p.a., including board, residence, and laundry. Applications, stating age, nationality, etc., together with copies of three testimonials, to be sent to the Secretary, endorsed "House Surgeon."

Conditions of appointment may be had on application to the Secretary.

Infirmary Office, Rochdale. W. WYNNE, Secretary.

Royal South Hants and Southampton Hospital.

Applications are invited for the appointment of HOUSE SURGEON and RESIDENT ANÆSTHETIST. Salary £140 per annum, with rooms, board, and laundry. Six months' engagement. Candidates, who must be male and unmarried, should apply to the undersigned, stating age, and enclosing copies of testimonials.

HY. TRUSSON, Secretary.

Altrincham General Hospital, Cheshire.

Applications are invited for the post of HOUSE SURGEON. Salary £125 per annum, with board, residence, and laundry.

The appointment is for six months in the first instance.

Applications, stating age and experience, together with copies of recent testimonials, to be sent in not later than Monday, November 25th, to WILLIAM MOODY, Secretary, 31, Market St., Altrincham, Cheshire.

University College Hospital, Gower Street, W.C.

Applications are invited for the honorary post of ANÆSTHETIST to University College Hospital for duty on four half days per week, and should be forwarded to the Secretary before noon on Tuesday, November 26th.

City of Worcester.

MEDICAL OFFICER OF HEALTH.

The Worcester City Council invite applications for appointment as Medical Officer of Health of the City.

The gentleman appointed must devote his whole time to his duties, and will act as Chief Tuberculosis Officer and take entire charge of the Public Health work of the City Council, including the Maternity and Child Welfare, Mental Deficiency, and School Medical services, and of the Council's Isolation Hospital and of City cases in the County Small-pox Hospital, and will also act as Supervising Officer under the Midwives Acts and Certifying Officer under the Council's Superannuation Scheme. He will have the assistance of: (1) the retiring Medical Officer as Consultant, who will take charge of the Isolation Hospital temporarily for the Medical Officer, and (2) a fully qualified whole-time Lady School Medical Officer, who will assist in the Maternity and Child Welfare work.

The salary will be £900 per annum.

Candidates must not be more than 40 years of age, and must be qualified as required by law.

The post will be an established post under the Local Government and Other Officers Superannuation Act, 1922.

A statement of the duties, qualifications, and terms of appointment will be forwarded on application to the undersigned.

Applications, accompanied by not more than three recent testimonials, must reach the undersigned not later than November 30th.

Canvassing, either directly or indirectly, will disqualify, but a candidate may send twenty copies of his application and testimonials for the use of the Health Committee.

SAMUEL SOUTHALL, Town Clerk.

Guildhall, Worcester. November, 1929.

Lurgan Union.

The Board of Guardians of the above Union will, at their meeting to be held on Thursday, November 21st, 1929, proceed to elect a duly qualified person to the position of MEDICAL OFFICER of the LURGAN No. 2 DISPENSARY DISTRICT of the Union, at a salary at the rate of £180 per annum, together with vaccination and registration fees.

The person elected becomes Medical Officer of Health of the district, and in respect of this a salary at the rate of £15 14s. 4d. per annum will be paid by the Lurgan Rural District Council.

A suitable residence (with garden attached and garage), in a central part of the district, has been provided by the Board, in which the person appointed will be required to reside and pay a rent of £16 per annum for same, with rates.

Applications, accompanied by certificate of registration and testimonials, will be received by me up to 10 o'clock a.m. on November 21st.

Attendance of candidates required on date of election.

By order,
J. CALVERT, Clerk of Union.

Clerk's Office, Workhouse, Lurgan. November 8th, 1929.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair { 1782 / 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

$C_8 H_{10} N_4 O_2 + H_2 O$

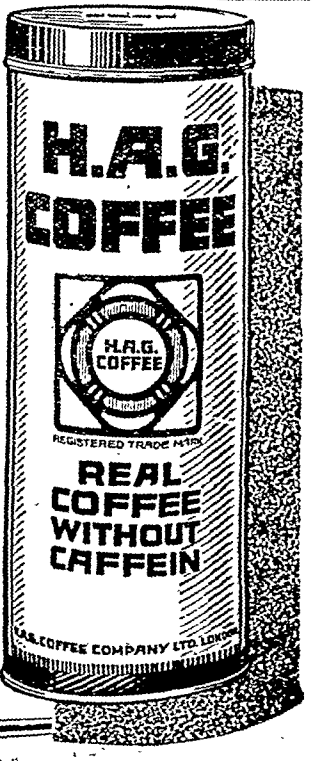
THE injurious action of caffein, to which the ailing, reconvalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE**, we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance



H.A.G. COFFEE CO. LTD.
40 Theobald's Road, London, W.C.1

The "Allenburys"

"*Perfected*"

Cod-Liver Oil

Cod-Liver Oil is the richest available natural source of the fat soluble growth-promoting and anti-infective vitamin ***A*** and the antirachitic vitamin ***D***.

The 'Allenburys' 'Perfected' Cod-Liver Oil is examined **biologically** and **certified fully active** with regard to **Vitamins *A* and *D***.

Examined by the Antimony Trichloride Test it gives a colour equal to **8-9 'Blue Units.'**

In amber bottles for protection against light at 1/3, 2/6, 4/6 and 8/6.

Descriptive literature and a clinical sample will be sent post free on application.

PNEUMONIA

TRANSPULMIN

A sterile solution of basic quinine and camphor in etheral oils. Provides the first painless method of injecting quinine in the treatment of

BRONCHITIS **PNEUMONIA** **BRONCHIECTASIS**

Especially useful for the prevention and treatment of pulmonary complications in Influenza, and in the treatment of Asthma.

It has been found in hospital practice that Transpulmin gives more relief in long-standing cases of emphysema than any other form of treatment.

In more than 1,000 cases of Pneumonia in hospital the mortality rate with Transpulmin was *less than half* that prevailing where other methods were used.

WHOOPING COUGH.

To control quickly the spasmodic coughing and vomiting, use the original ELIXIR of EPHEDRINE (Abbott)

4-oz. bottle - 3/-

In ampoules of 1.2 c.c. and bottles of 25 c.c.

SAUNDERS' BOOKS

Cecil's Text-Book of Medicine

"The plan of presenting a text-book in which a large number of authorities have collaborated has obvious advantages to the student preparing for his final examination, and to the practitioner of more mature years seeking recent and reliable information. Dr. Cecil is to be congratulated on the success with which he has brought this magnum opus into being."
—BRITISH MEDICAL JOURNAL.

By 130 Authors. Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical School. Octavo of 1,500 pages, illustrated. Cloth 40s. net.

MacCallum's Text-Book of Pathology

"No doubt this book has often been taken down from the laboratory shelf to verify some small point, not to be replaced immediately the information sought has been obtained; it is apt to beguile the reader, enticing him to some stimulating thought. It teaches ideas rather than facts."—BRITISH MEDICAL JOURNAL.

By W. G. MACCALLUM, M.D., Professor of Pathology and Bacteriology, Johns Hopkins University. Octavo of 1,177 pages, 606 original illustrations, 50 in colours. Cloth, 45s. net.

Howell's Text-Book of Physiology

"It is an encouraging sign of the times that a text-book so remote from any approach to the cram-book should have gained so much popularity with the medical student . . . The author has succeeded in making his subject-matter interesting and in many parts fascinating—an art deplorably rare in physiological writings. The book inspires respect rather than criticism."—EDINBURGH MEDICAL JOURNAL.

By WILLIAM H. HOWELL, M.D., Ph.D., Professor of Physiology, Johns Hopkins University, Baltimore. Tenth Edition. Octavo of 1,081 pages, illustrated. Cloth, 30s. net.

McGuigan's Text-Book of Therapeutics

"Professor McGuigan has succeeded in producing something quite different from the usual run of books on pharmacology and therapeutics suitable for undergraduates. . . . One can unhesitatingly recommend the book to the attention of students of medicine in search of an accurate book of reasonable dimensions."
—SOUTH AFRICAN MEDICAL JOURNAL.

By HUGH ALISTER MCGUIGAN, Ph.D., M.D., Professor of Pharmacology and Therapeutics, University of Illinois College of Medicine. Octavo of 660 pages, illustrated. Cloth, 28s. net.

Babcock's Text-Book of Surgery

"Takes a distinguished place among the many general text-books that are available. It is designed both for the student and the practitioner, as the author believes that, with the increase of clinical teaching and the declining importance of systematic lectures, the student must turn more to his reading for his theoretic background."
—BRITISH MEDICAL JOURNAL.

By W. WAYNE BABCOCK, M.D., Professor of Surgery, Temple University, Philadelphia. Octavo of 1,367 pages, with 1,050 illustrations, 9 in colours. Cloth, 45s. net.

Boyd's Surgical Pathology

"Accurate, clear, and well illustrated. . . . An unusual but commendable feature for a book on pathology is the summary of symptoms which accompanies many descriptions, thus providing a link between the laboratory and the clinical sides. . . . The book is well described by Dr. W. J. Mayo as 'a sincere attempt to place pathology before the student and practitioner from the practical standpoint.'"—BRITISH MEDICAL JOURN.

By WILLIAM BOYD, M.D., M.R.C.P.Ed., F.R.S.Can., Professor of Pathology, University of Manitoba. Octavo of 933 pages, with 476 illustrations, and 15 coloured plates. New (2nd) Edition. Cloth, 48s. net.

Arey's Developmental Anatomy

"Professor Arey has published a text-book which includes more post-natal development than most other manuals of embryology. The outline presented of the more important developmental changes manifested after birth is a very valuable addition . . . Professor Arey is to be congratulated on the production of a text-book of embryology which may be highly recommended and is likely to be used very widely." BRIT. MED. JOUR.

By LESLIE BRAINERD AREY, Professor of Anatomy at the Northwestern University Medical School, Chicago. Octavo of 433 pages, with 419 illustrations, many in colours. Cloth, 27s. 6d. net.

Sollmann's Manual of Pharmacology

"Of particular value to advanced students because a full account is given of the chief recent research work in the subjects dealt with, and moreover an excellent selected bibliography of a hundred pages is included. . . . The most extensive work of reference in pharmacology in our language."
—BRITISH MEDICAL JOURNAL.

By TORALD SOLLMANN, M.D., Professor of Pharmacology in the School of Medicine of Western Reserve University, Cleveland. Octavo of 1,184 pages, illustrated. Cloth, 35s. net.

9, Henrietta Street LONDON, W.C.2 **SAUNDERS** 9, Henrietta Street LONDON, W.C.2

THE ADRENALS

THEIR PHYSIOLOGY, PATHOLOGY, AND DISEASES

By MAX A. GOLDZIEHER, M.D., Former Prof. of Pathology, Univer. of Budapest.

LONDON: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1.

Greater Comfort for Your Patients.

"The Rose Corset-Belt"

which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

Lounge Suits *for* Doctors

£1 PER MONTH

Appearance is everything to the professional man, as nothing enhances status so much as good attire.

Most tailors study price, fit and finish, but few care what happens to your clothes after purchase, whereas Keith Bradbury [illegible] after purchase; garments are collected, brushed, repaired, sponged, pressed and returned like new.

Every consideration is given to the financial convenience of Doctors, who, more often than not, have to wait indefinitely for settlement of their own accounts. Arrangements are made whereby accounts can be disposed of half-yearly, quarterly, upon a £1 a month basis, or in any other way to suit individual requirements.

Distance need be no barrier to country practitioners, as the comprehensive Keith Bradbury self-measurement chart assures a perfect fit of all West End garments supplied by post—and to convince you that our confidence in this through-the-post service is not misplaced, we undertake to give you complete satisfaction or re-make the garments ordered.

An illustrated catalogue, patterns or full particulars of our special financial facilities will be gladly sent upon receipt of a postcard or telephone message, or, perhaps you prefer to call and see us.

ENSURE THAT YOUR SUN-RAY TREATMENT PATIENTS CONTINUE TO **LIVE** IN AN **ULTRA-VIOLET RAY** ATMOSPHERE

Holviglass has been proved by scientific and practical experience to be an ideal medium for bringing the rays indoors from sun or sky. It is the most scientific and perfect "health glass" made, and is fully guaranteed by Holophane Ltd., illuminating engineers and experts in scientific glass-making for over 30 years.

Important sanatorium authorities have equipped extensive roof gardens with ultra-violet ray glass, so that patients continue their post-clinical treatment by living in an atmosphere of U.V.R.

Sanatorium, Clinical, and Hospital authorities are invited to consult Holophane Limited as to the comparatively small cost at which wards and conservatories, housing sun-ray patients, can be equipped.

Guaranteed HOLVIGLASS is supplied in sheet and cathedral form at a fractional additional cost of ordinary glass, through Builders, Glaziers, and Glass Merchants everywhere.

Fully descriptive Illustrated Brochure A63 and prices sent free on application.

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

The Source of NOURISHMENT

VITAMIN B

Outstanding advantages of HOVIS

Of all kinds of bread consumed to-day, HOVIS is richest in Vitamin B, which encourages growth and increase of weight. Bulk for bulk it supplies a greater amount of nourishment.

HOVIS combines all the benefits of white flour with 25 per cent. of the wheat germ, the part richest in the vitamin, added.

Compared with other cereals, the Vitamin B content of milling products and yeast in 100 g. dried bread is as follows:

White Bread	200
Wholemeal Bread ...	1,450
HOVIS Bread	2,600

The great value of HOVIS is that it contains all the elements of a complete food; it is universally liked, and containing no bran is easily absorbed.

It is also most economical, the quantity necessary to furnish sufficient nourishment being very small.

Were HOVIS to form a part of everybody's daily diet the nation would undoubtedly be better nourished.

AROMATIC CASCARA.

An agreeable and physiologically active preparation almost devoid of bitterness, which represents the therapeutic virtues of Cascara Sagrada.

PRICE 6/6 lb.

FULL LISTS ON APPLICATION.

AN ADVANCE IN THE SCIENCE OF DERMATOLOGY

Lessons learnt during the Great War have been having their full effect during the past few years. In no sphere of medical research is this more evident than in Dermatology. For instance, it can now be truthfully said that the peat distillate principle, so intensively tested in the hospitals in war time, has gained the favour of the greater number of medical practitioners in this country.

Having this fact in view, Peat Products Ltd. produced an ointment containing the peat distillate principle, all the therapeutic qualities of Sphagnum moss, in an easily administered form. They call this ointment "Sphagnol," and it can be bought at any chemist's. It is backed by Sphagnol lotion, soaps, and suppositories, which also contain the peat distillate principle.

If you would like to test these products please write for samples to Peat Products (Sphagnol) Ltd. (Dept. B18), 21, Bush Lane, London, E.C.4.

Intestinal Disinfection

HYPERPIESIS

HYPERPIESIS is described as "a malady in which blood pressure rises excessively, a malady having a course of its own and deserving the name of a disease."

A writer in THE LANCET describes cases of this condition, and ascribes its causation to toxic substances of the nature of which he is uncertain, but which he believes to be extra-renal in origin and to be distributed by the blood stream.

It seems highly probable that these substances are the "pressor" substances such as epinephrine, which are developed by putrefactive bacteria in the intestine. Assuming the truth of this likely hypothesis, the treatment in part should obviously consist in adequate intestinal disinfection.

Certain compounds of the coal-tar series, having high germicidal value and little solubility in the alimentary tract, pre-eminently possess this disinfecting power and form the active constituents of Kerol, which may be given in a palatable form by means of keratin-coated capsules which ensure disinfection of the alimentary tract without deleterious effect.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

"I have required no aperient since taking BEMAX"

Co. 17. "Within 8 or 10 days the effects on constipation were marked. I have required no aperient since taking Bemax."
—M.D.

Co. 10. "After a fortnight I was able to give up taking Pil Aloes et Ferri, which I had taken for years, I also put on weight. I found two dessertspoonfuls taken with porridge very palatable."
—M.R.C.S., L.R.C.P.

BEMAX gives very satisfactory results in cases of chronic constipation. The two reports quoted are taken from hundreds which have reached us from medical men. A tablespoonful of Bemax a day supplies the proportion of 'B' Vitamin required by an adult to restore balance of nutrition; consequently Bemax is an invaluable remedy for Intestinal Toxæmia, Debility, Neurasthenia, Gastric Disturbances, and other ailments due to vitamin deficiency.

We shall be pleased to send free a full size tin to any medical man on receipt of his professional card. Over 34,000 members of the medical profession in Great Britain have applied for Bemax for personal trial.

In the treatment of

Asthma and Whooping-Cough

The success which has attended the use of ephedrine in recurrent asthma and whooping-cough has led to the adoption of this form of therapy as the routine treatment in general practice.

Maximum therapeutic effects with complete elimination of toxic symptoms result when naturally-occurring ephedrine free from pseudo-ephedrine is used.

Ephedrine B.D.H., which is made by a special process from the Chinese plant Ma Huang, produces such maximum therapeutic effects with no attendant toxicity.

Dimol

in Enteric Epidemicity

Causation is always difficult, and often impossible, to discover, but it seems a reasonable procedure, in epidemic areas, to assist prevention by the use of an intestinal bactericide. Dimol is non-toxic to any part of the alimentary mucosa, yet one grain has a bactericidal potency for cultures of B. typhosus equal to thirty-five times that weight of pure phenol.

The Dimol Laboratories are prepared to demonstrate to any properly constituted committee of the Medical Profession that a pure culture of this bacillus can be swallowed, and the germs destroyed in the stomach by the action of Dimol pulverettes, taken immediately after the culture.

The efficiency of Dimol in the treatment of many other intestinal conditions of bacterial origin is conclusively told in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any physician on application to—

The Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

Telegrams—"PHARSALIA, PHONE, LONDON." Telephone—MUSEUM 5440.

"By its palatability and general excellence 'Roboleine' has taken the high rank to which it is entitled among dietetic aids."
The Lancet.

"A perfect food for brain, muscle, and bone. It can be taken by the most fastidious and never nauseates."
The British Medical Journal.

"The value of this preparation to the marasmic or debilitated child is too obvious to call for discussion."
The Medical Annual.

BECAUSE of its VALUE in cases of Malnutrition, Debility, Sleeplessness, Loss of Weight, in all cases of Tuberculosis conditions, Nursing and Expectant Mothers as a galactagogue, and as an adjunct in the dieting of infants, the output of

ROBOLEINE

increases month by month. Moreover, it can be taken by the most fastidious and rarely nauseates.

Sample sent gladly on request.

A product of

Oppenheimer, Son & Co., Ltd.,
Handforth Laboratories,
Clapham Road,
London, S.W.9.

ROBOLEINE contains all essential vitamins:—

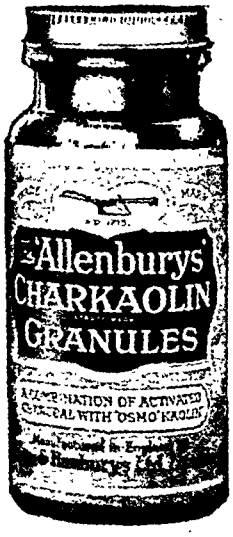
BONE MARROW to make good red blood and increase resistance to disease, and strengthen the whole nervous system.

MALT, a natural laxative and source of energy.

EGG YOLK containing Lecithin, the greatest nerve food known.

LEMON JUICE neutralised for building bone and preventing skin troubles.

The 'Allenburys'



'CHARKAOLIN' GRANULES

A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

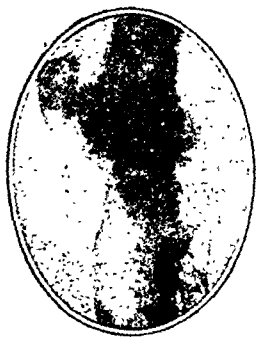
'IODOLYSIN'

Trade Mark

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready Solubility in water. Well tolerated. Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Radiograph of Hip-joint in Rheumatoid Arthritis

MADE WITH THE METICULOUS CARE THAT FIRST BROUGHT THEM FAME NEARLY A CENTURY AGO

FOR nearly a century, doctors have testified to the stimulating and restorative properties of Brand's Meat Essences.

In states of exhaustion and when patients have little or no appetite, a diet of Brand's Essence will restore vitality without strain on the digestive organs and prepare patients for a more solid diet.

BRAND'S ESSENCES

By an exclusive process and under perfect hygienic conditions, the juices of the finest freshly killed chickens, beef and mutton are extracted to make Brand's Essences. No other substance is added—the pure essences containing the phosphates and stimulating properties of the meat go straight to the consumer.

Brand's Essences (Beef, Chicken and Mutton) are obtainable at chemists and stores throughout the world in small and large-sized tins and jars. Brand & Co. Ltd., Mayfair Works, Vauxhall, London, S.W.8.

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific. It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A valuable asset in Treating Nervous Ailments

Every Doctor knows the value of specific treatment in illness, and one of the greatest difficulties in treating nervous troubles hitherto has been the absence of a specific remedy for debilitated nerve cells and tissues.

"NEW-PROMONTA" is not only a specific remedy, but also a very speedy and reliable one, as has been proved by exhaustive tests in many hospitals and clinics and in private practice.

The active agents in "NEW-PROMONTA" are the Lipoids, Phosphatides, and Cholesterols, which by a special process of preparation are preserved intact and in the same quantity as they are found in the living cells of nerves and brain.

"NEW-PROMONTA" is valuable in other directions. It contains a high proportion of concentrated nutritives, including Lime, Iron, Hæmoglobin, and the Vitamins A, B, D, and E. It is therefore a powerful factor in promoting general robustness, in counteracting the after-effects of illness, and during convalescence.

TO TEST "NEW-PROMONTA."

A trial supply of "NEW-PROMONTA," together with a collection of authoritative data on its composition and the tests to which it has already been subjected, will be sent post free to any Doctor, Clinic, or Hospital on application.

"NEW-PROMONTA" in Tablet form is supplied in handy boxes containing 54 tablets at 3/6. Each box includes a metal container for the pocket, which holds a day's supply.

"NEW-PROMONTA" in Powder form is supplied in sealed air-tight boxes of ¼-lb. at 3/- and ½-lb. at 5/6.

National Committee for Promoting the Consumption of Norwegian Cod Liver Oil, Bergen, Norway.

COD LIVER OIL ABOUNDS IN NATURAL VITAMINS.

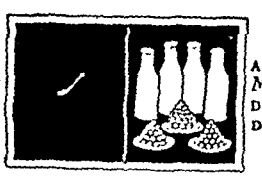
Norwegian Cod Liver Oil stimulates growth, prevents or cures rickets, gives increased protection against epidemics and wasting diseases such as consumption. Cod Liver Oil maintains strength, assists recovery after illness, builds up the system and restores health, gives vitality and strength.

Every Doctor and every Nurse knows this. But new and important properties of cod liver oil are constantly being discovered. Thus in its Special Report No. 134, the British Medical Research Council states:

"On the Archangel front during the war, night-blindness amongst the troops was a common occurrence. The condition yielded to treatment with cod-liver oil, which contains vitamin A."

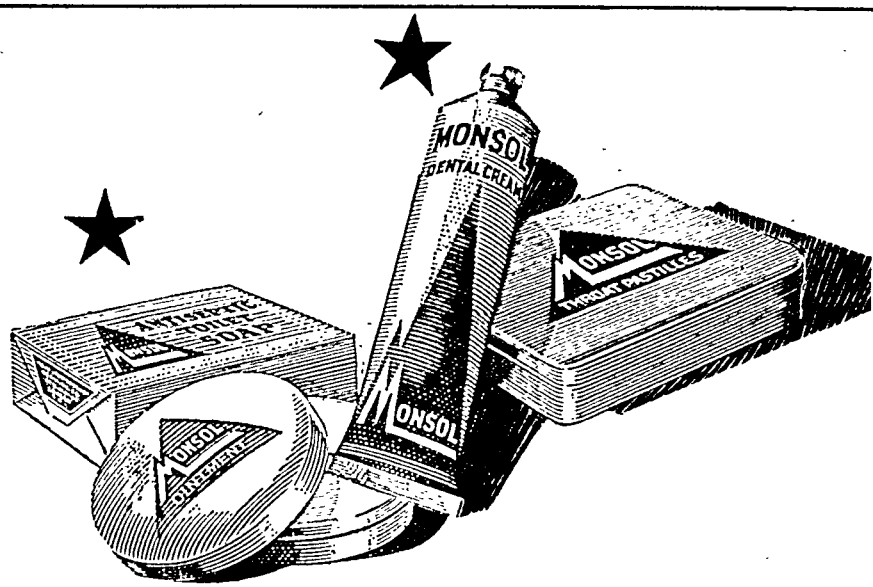
In your practice perhaps you have discovered some other way in which cod liver oil is useful. If so, please write and tell us about it so that we can place your knowledge at the disposal of the Medical Profession.

A TEASPOONFUL OF NORWEGIAN COD LIVER OIL CONTAINS MORE VITAMINS THAN



ALL THE BUTTER AND MILK ANY INDIVIDUAL CAN EAT AND DRINK IN A DAY

NORWEGIAN COD LIVER OIL



The manufacturers of MONSOL confidently recommend these new TOILET PRODUCTS to members of the medical profession for personal use

The profession has already exhibited great confidence in the prophylactic value of Monsol Pastilles—many doctors find them the only convenient method of adequately disinfecting the mouth and throat. Now that we have Produced a new Monsol Dental Cream and Toilet Soap . . . . .

MONSOL DENTAL CREAM 1/- per large tube

BRAND

MONSOL TOILET SOAP 8d per tablet

BRAND

. . . both modern products in the best sense of the term, and both containing a really effective proportion of Monsol, we have no hesitation in urging medical men to incorporate them in their toilet, as one of their routine measures against personal infection. Pleasant to use, and very mild, although of high germicidal value, these products afford further evidence of the unique properties of Monsol—the most powerful SAFE antiseptic.

NATURALLY RICH IN VITAMIN 'D'

"SMILER"

Intensive investigations into the use of synthetic vitamin D preparations have not yet been completed, but the possibility of hypervitaminosis has already been definitely established, and the dangers of excessive prescribing have been demonstrated.

Cow & Gate Milk Food

"Cow's Milk made safe and suitable for Baby."

In the irradiation of milk so many factors are involved besides those of the production of vitamin D that up to the present authorities have agreed that its use is not permissible except under carefully controlled conditions. Vitamins D occurs in sufficient quantities in fresh milk from cows fed on the rich pastures of the West of England; and such milk, when dried by the improved COW & GATE roller process, suffers no appreciable loss of vitamin D. The result is a clean basic milk containing *natural* vitamin D in adequate proportions for the maintenance of perfect and healthy growth. Physicians recommending this product avoid the risk of unknown factors and are prescribing a pure and unadulterated preparation of the highest repute, which has been used with outstanding success for over a quarter of a century.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

COW & GATE Ltd.,

GUILDFORD.

RADIO-MALT

For the Preservation of Disease-Resisting Power during Autumn and Winter

IT is generally recognised by the medical faculty that the incidence of epidemics in the New Year is due, principally, to the fact that the reserves of resisting power, having been drawn upon during the Autumn and early Winter, are left exhausted; consequently, there is no supply available to withstand the onslaught of germs of virulent diseases prevalent in January and February.

The discovery of the valuable anti-infective properties of Radio-Malt is of considerable importance in this connection. In Radio-Malt the physician has ready at hand a preparation which not only helps to build body tissue by promoting correct assimilation of food, but gives protection against the attacks of infectious diseases.

It is on account of its disease-resisting properties that Radio-Malt acts as such a valuable safeguard when given regularly during the winter months to those who, through force of circumstances, are compelled to spend a considerable proportion of their time in crowded places such as offices, workshops, schools etc. Radio-Malt has proved particularly valuable also for daily administration throughout the Autumn and Winter to expectant and nursing mothers, to growing children, to convalescents and, indeed, to all who are in need of daily replenishment of the power to enable them to resist infection.

Vit. Pr./I

The Original & Standard
Emulsion of Petroleum

Angier's Emulsion

is made with petroleum specially purified for internal use. It is the original petroleum emulsion—the result of many years of careful research and experiment.

In Gastro-Intestinal Disorders

of a catarrhal, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful. The minutely divided globules of petroleum reach the intestines unchanged, and mingle freely with intestinal contents. Fermentation is inhibited, irritation and inflammation of the intestinal mucosa rapidly reduced, and elimination of toxic material greatly facilitated. An improved state of the digestive functions and modifications of the various symptoms traceable to auto-intoxication are notable results.

During Convalescence

After fever, dysentery, operations, or after any serious illness, Angier's Emulsion will improve and strengthen the organs of digestion and assimilation and enable patients to derive the fullest benefit from any prescribed diet. The creation of appetite and the return of normal digestion is quickly brought about by its regular use.

Frail, Nervous Patients

respond actively to Angier's Emulsion. It is a tonic in effect and an aid to digestion. Being a perfect Emulsion, it is presented in a form pleasing to the taste and acceptable to the most fastidious. Its good effects are accomplished in a safe and natural manner without entailing any extra work upon the weak or overburdened system.

PLURIGLANDULAR DISPENSING

The growing and varied needs of the profession in this respect are well catered for in our Organo-therapeutic Dispensary. A complete range of Gland Substances is always in stock and prescriptions can be promptly and accurately dispensed. The following are two of our recognized formulæ.

THYROSEX Co.

Thyroid sicc. ... ... gr. 1/4
Whole ovary sicc. ... gr. 1/2
Whole pituitary sicc. ... gr. 1/10

This represents one average dose and is contained in one Tablet (O.T.M. 520) or in one drachm of the Elixir (O.T.M. 530).

Thyrosex Co. (Evans') is designed for the treatment of the sexual disorders of puberty and for the neuroses and psychoses of menstruation. It is also well worth a trial in mental disorders associated with the menopause, in the treatment of acne at puberty, in skin affections occurring during pregnancy, and in certain cases of obesity, especially in women.

MAMMARY Co.

Mammary sicc. ... ... gr. .1
Whole pituitary sicc. ... gr. 1/2

This represents one average dose and is contained in one Tablet (O.T.M. 590) or in one drachm of the Elixir (O.T.M. 595).

In this formula the antagonism of the mammary gland and the ovary is utilised for the treatment of those conditions arising out of hyperactivity of the ovary. Its use is particularly indicated for older women. Mammary gland substance has been found useful in relieving the symptoms of uterine fibroids, metrorrhagia following functional neuroses associated with hyperovarism, and uterine hæmorrhage generally, especially when administered in conjunction with ergot.

Full particulars of these and other formulæ will be found in our *Brochure on "Pluriglandular Function,"* which may be had on application to—

Evans' Biological Institute, Puncorn.

The Standard of Purity of

INSULIN "A.B."

TRADE A B MARK **Brand**

The ideal Insulin should be so pure that its use is entirely free from any untoward effect. This is the aim of the makers of Insulin "A.B.", who have adopted their own stringently high standard of purity and have always maintained it. Reductions in their prices have *never involved the slightest sacrifice of quality.*

Insulin "A.B." is so pure—and therefore so free from reaction-producing proteins—that the number of clinical units per milligram of substance approaches the maximum possible, i.e., the equivalent of crystalline Insulin.

The world-wide supremacy of Insulin "A.B." is due to this unequivocal purity no less than to its well-known potency and stability under all conditions.

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position not by extravagant or sensational advertising but by the constant recommendation of medical men and women. To-day it is universally used not only at home but throughout the world. Few foods have so enjoyed the approbation of the Medical Profession for over 40 years.

Benger's Food differs from all other foods in that it is especially prepared to adjust fresh cows' milk or cows' milk and water so as to suit the condition of any patient. While it is largely used as a routine treatment in all cases of disordered digestion the following comments, which have been recently made by Doctors, indicate some specific uses to which Benger's Food has been put.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

Observations on THE TREATMENT OF SCOLIOSIS.*

BY

D. McCRAE AITKEN, M.B., Ch.B., F.R.C.S.,

SURGEON, SHROPSHIRE ORTHOPAEDIC HOSPITAL AND ST. VINCENT'S ORTHOPAEDIC HOSPITAL.

THE treatment of scoliosis is the subject of our discussion to-day. I should have preferred the title to be "the principles of treatment," and propose to dilate rather on this aspect, leaving others to fill in gaps.

Scoliosis has been one of the most difficult problems in orthopaedic practice from the beginning. Different authorities proclaim the merits of their own methods, and I fear you will say I am no better than the others. I cannot, however, honestly set the subject before this meeting unless I endeavour to present it as I see it and as I have discovered it for myself in practice. I trust, however, that I shall be able to show that all depends on following definite fundamental principles based on sound and established rules of anatomy and physiology. If sound basic principles can be established, any treatment which is in agreement with them cannot be far wrong, and any treatment which clashes with them calls for a revision either of the method of treatment or of the theory of principles, to discover where the fault lies.

More than twenty years ago Sir Robert Jones said to me: "You have grasped my principles of treatment of deformity by continuous retention of correct position while recovery of muscular function is taking place. You are interested in scoliosis: go ahead and see if you cannot find out how to apply the same principles to scoliosis."

If this discussion is to be of service to future workers we must endeavour to establish principles for the treatment of this deformity which are consistent with established principles which we know to contain a considerable measure of truth and have been proved to have some practical value.

Before I go further let me make acknowledgement and apology to all whose ideas I have borrowed; I may have forgotten some sources from which I borrowed. For example, when I wrote an essay on scoliosis in the *Robert Jones Birthday Book* I thought that the importance I attach to what I called unilateral lordosis was probably original. On looking through William Adams's lectures on curvature of the spine, I find he pointed out in 1854 that rotation is an essential part of scoliosis, and—for example, in the lumbar region—once rotation has occurred any increase in the lordosis increases the lateral displacement; so that idea is in no way new, though there may be something new in the application of it. In 1907 or 1908, when I was in some despair of mind about really getting any further with the treatment of scoliosis, I read an article by Dr. Michael Hoke, which, like everything else from his pen, proved illuminating. His observation was that during respiration a scoliotic patient expands the bulging parts of the chest more freely than the flattened parts, and that movement, owing to the articulation of the ribs with the vertebrae, tends to rotate the vertebrae further in the direction of the rotation deformity. The second part of his observation was that these bulges are at the ends of an oblique diameter—that is, that a right posterior hump is associated with a left anterior bulging in the front of the chest. Hoke's next point was that compressing these humps restrained their movement, that the flattened parts immediately began to move more freely, and that this increased movement helped to turn the vertebrae in a direction opposite to that of the rotation deformity.

So far as I personally am concerned, I count the publication of Michael Hoke's paper as the epoch marking the beginning of a new era of hope and of progress.

For twenty years, therefore, asymmetrical breathing exercises as a voluntary effort, as well as jackets applied to enforce asymmetric breathing, have been an essential part of my practice. Next, in practising how to get asymmetrical breathing, it comes out that the body weight must be unevenly distributed on the two feet. To expand the right side of the chest more fully than the left the body weight is carried more on the right foot than on the left. This statement may sound new to some, but the fact has been known since the first oarsman handled a pair of sculls, for in order to turn the skiff we are taught, not to pull harder with one arm, but to press harder with one foot, and the corresponding shoulder will do the rest. The origin of this oarsman's precept is lost in the mists of antiquity, but it is in itself a tacit expression of belief that all our muscular movements are reflexly associated. It was while I was house-surgeon that Magnus, now a professor in Utrecht, was experimenting in reflexes in Professor Sherrington's laboratories. His work laid the foundation of the modern doctrine of the postural reflexes, which underlies our modern way of looking at orthopaedic problems—which are the same problems as those our forefathers faced.

The doctrine of the postural reflexes is, briefly, that every animal stands, walks, and generally controls its locomotive system by means of a complex reflex control of muscles which is so highly trained that it goes on automatically without conscious thought—that is, without brain fag or fatigue.

It was only three or four years ago, in the course of a casual conversation, that Professor Sherrington dropped into my mind two words which suddenly crystallized my rather mixed ideas on scoliosis, and helped me to set them in order. While discussing posture I had mentioned my idea that teaching of breathing exercises was much neglected or was often wrong. His reply was: "It is a curious thing that we should need lessons in breathing, for it is the oldest of these reflexes." The two words are "these reflexes."

First we learn to breathe and make a confused noise; then we learn to sit and balance and walk; we also learn to talk, to read, to write, and so on by automatic reflex without fatigue. The untutored savage reads the movements of animals as you and I could never hope to do, for he practises the art till it is absolutely subconscious. If he comes to a difficult passage he may have to stop to think, and puzzle out the meaning of a mixed trail, but so do you and I, each in our particular station in life.

There are exceptions, of course, to this automatic learning. The deaf-mute does not learn to talk because there is a flaw in the nervous cycle, but he can be taught by the lip-reading process. The child with a congenital spastic paralysis does not learn to walk, but if you can get him in an erect posture with the soles of his feet on the ground you may be able to teach him to acquire postural reflexes and to walk, and the earlier we set about this re-education the better.

All athletic training is training of reflexes. I go further, and say that training of inhibition is often more important than training of contraction, for it is the quick relaxation and recovery which makes for speed and alertness—that is, delicacy of co-ordination.

Scoliosis has been defined as a rotato-lateral curvature of the vertebral column. It is often spoken of as lateral curvature to distinguish this deformity from round back and hollow back. To think of scoliosis as a lateral curvature is fatal to successful treatment. Personally I made no progress till I put rotation first. Scoliosis, to my mind, is a twisted asymmetrical trunk, and this twist is inevitably associated with lateral deviation, with asymmetrical kyphosis, and asymmetrical lordosis. This necessarily means an upset of all that symmetrical muscle balance by which the posture of the body is maintained.

The cause of scoliosis is any disturbance which upsets the symmetrical co-ordinate reflex action of muscles controlling posture. A transitory broncho-pneumonia may cause a visible scoliosis in a few weeks, due to asymmetrical breathing (as Biezalski pointed out nearly twenty years ago). I have repeatedly seen the deformity associated with appendicitis. One girl attributed her own deformity

*Made in opening a discussion in the Section of Orthopaedics at the Annual Meeting of the British Medical Association, Manchester, 1929.

to a sore heel. Inquiry showed that two years previously she had an inflammation of the epiphysis of one os calcis, confirmed by contemporary x rays, fortunately of both feet for comparison. Two years later the girl still prefers to walk more firmly on the sound heel, and I am trying to teach her to reverse this habit as the first factor in correction.

METHODS OF TREATMENT.

The treatment of scoliosis must therefore mean the restoration of symmetrical postural balance, or as near it as we can attain, first by eliminating every extraneous factor which may have originated an asymmetrical balance; secondly, by re-educating all postural reflexes, including the respiratory, after correcting gross deformities if this can be done. The methods of treatment at our disposal are:

1. Exercises and training in posture and balance. This method comes first and last and all the time.
2. Assisting postural exercises by twisting the trunk into a more correct position and retaining it by means of splints or jackets while the postural reflexes are being trained.
3. Operative methods of treatment.

I will take these three methods in reverse order.

Operative Methods.

Ninety years ago Guérin of Paris made a practice of "dividing the muscles on one side of the back." To-day, in cases where skeletal position cannot be maintained in corrected position, bone fixation of the vertebral column is being practised. I have no personal experience of spinal fixation except in cases of osseous disease. In paralytic cases I have up to the present contented myself with using jackets. Such operations are chiefly for cases not amenable to curative treatment and therefore outside my main argument on principles of treatment.

Maintaining the Body in a Corrected Position while Training the Postural Reflexes.

It is in the second group that my personal interest has been most engaged—namely, in endeavouring to hold the body in a corrected position while balance and postural reflex is being restored, and perhaps some measure of adaptive change in the osseous structures takes place. The question is, What can we try to do by means of jackets and what do we actually achieve?

1. By forcibly correcting the shape of the trunk and then applying a plaster jacket we may hope to produce some real correction of deformity or of disability.

2. By jackets and supports we often hope to prevent the deformity from getting worse. These jackets are generally made by instrument makers, and to these is too often left the preparation of the casts from which they are made. It is in my experience extraordinarily difficult to get a cast made on which a removable jacket can be modelled which will put the patient in a position in which postural reflexes and respiration will help further to cure the deformity. Sometimes it can be done. There are also jackets made of steel with pads whose tightness of fit can be adjusted. Of the use of these I have little personal experience, but I have seen improvements in deformity produced by such apparatus when controlled by expert hands. Such apparatus is expensive, and I think more applicable to the more or less hopelessly deformed adult than to the young and the growing.

3. In too many instances jackets do harm. They are wrongly designed, and put the patient in the wrong posture, so that they assist rather than prevent increase of deformity or relapse in cases in which some correction of deformity has previously been obtained.

I would therefore divide jackets or apparatus into two classes: (*a*) those intended primarily to produce correction of deformity, which we may call corrective jackets; (*b*) those merely intended to retain shape and position already secured. Such retentive jackets to be really successful must have incorporated in their shape and construction some of the elements essential to corrective jackets.

Now what are the points essential to a corrective splint? Here I beg leave to go back to the beginning and deal with splints as I was taught to use them in Liverpool. Take for argument a straightforward case of dropped wrist. The treatment is to put the wrist and hand in such degree of dorsiflexion as can be obtained without leaving the patient in pain from overstretching of flexor structures, and to maintain this position till the tight structures get looser. I used at one time to think of this as "stretching shortened muscles"; to-day I prefer to think of it as restoration of the inhibitory reflexes in the habitually contracted muscles. Now comes the important point. When I was house-surgeon in Liverpool, in the days when Sir Robert Jones handled his out-patients with his own hands, I was taught that the splint and bandages must be so applied as to prevent flexion, but not in any way to obstruct further extension. This is a point often overlooked or omitted.

In applying a splint or plaster jacket to correct scoliosis the same rule must be followed. The splint or jacket must in no way impede movements in the direction of correction of deformity, but must absolutely prevent relapse towards the original deformity, and must conform to our known standards which control postural reflexes.

For the purpose of argument and illustration of principles, I shall assume we are dealing with the usual right dorsal left lumbar deviation; also, for the purposes of our present argument, that there is no gross disease of bone and no paralysis.

A woodcut of the post-mortem appearances of scoliosis which differs in no material respect from those in modern books may be found in the works of Fabriccius Hildanus, who practised in 1500. It shows the rotation of the vertebrae, the lumbar lordosis, the dorsal kyphos, and the consequent lateral deviation.

I have already said that scoliosis must be regarded as a distortion of the whole trunk—a distortion of ribs and vertebrae and of co-ordinated muscular balance. In arriving at my present point of view I recognize three masters.

First, Dr. Michael Hoke, who in 1904 taught us that the asymmetrical excursion of the ribs in scoliosis is a dominant factor in maintaining and increasing the rotation deformity in the thoracic region.

Following up this idea, from 1908 onwards I was getting some results, and was clumsily groping for some means of getting more flexion of the trunk, when Dr. Abbott published his two papers in which he laid stress on the importance of full flexion in combination with breathing windows, which are essentially Hoke's idea. Now to my mind the great value of Abbott's method is that in fully correcting the lumbar lordosis we indirectly correct some of the lateral deviation in the lumbar region. As Adams pointed out in 1854, lumbar rotation combined with lordosis means lateral deviation.

The third master is Professor Patrick Haglund of Stockholm. His principle is to correct the lateral lumbar curve by pushing the trunk right over to the left, and the patient's own sense of balance will make him correct the dorsal curve by his own effort. In this I recognize the respiratory reflex as part of our postural reflex system. The scoliotic with a left lumbar right dorsal scoliosis generally stands more on the right foot than on the left. Professor Haglund pushes the patient bodily over on to the left foot and lets the patient's postural and respiratory reflex complex do the rest.

The jacket I now employ combines, I think, elements borrowed from all three of these authorities, and is consonant in principles with the teachings of Sir Robert Jones and with at any rate my present ideas on postural reflexes.

Exercises and Training in Posture and Balance.

I shall make no attempt to go into details of exercises. Classifying cases of scoliosis by the apparent deviation of the tips of the spines from the middle line is vicious. To try to apply routine exercises to cases classed as C or S curves is dangerous. The C curve often has a double rotation, one to left and one to right, and is really what is commonly called transitional. If this diagnosis is missed and a mere routine treatment adopted the case may rapidly develop into a really bad double curve. I have made this mistake more than once. Therefore to-day I do not accept any curve as a simple C curve. It is the rotation or twist

of the trunk that matters, not the apparent deviation of the tips of the spines of the vertebrae. One must therefore take the long view, and be ready to adopt a line of treatment which anticipates the oncoming deformity, and not be deceived by the apparent deformity. We have to deal with the same fundamental principles, whether we are dealing with early cases in which the patient can by *voluntary effort correct the apparent deformity*—the type of case sometimes called "postural," but this word is here used with a meaning wholly different from that attached to it in the phrase "postural reflex"—or with more advanced cases in which the patient cannot voluntarily correct, but the surgeon, by using external force, can correct the apparent deformity which some would call "early structural"; or with cases of a third type with gross bony changes or paralysis of nerves supplying muscles.

The first type may be cured by any intelligent system of exercises which helps the patient to correct the deformity automatically and not only by a conscious effort of will.

The second type may be corrected if the surgeon can first correct the deformity by external force which holds the patient in corrected position by means which prevents relapse but in no way impedes further correction. This must be followed by re-education in posture by means of exercises, which must become automatic to be effective.

The third type can only be pushed into some sort of vertical position and sometimes held there, so that the patient can hold an erect posture with one gross deformity more or less compensating another; but the main line of the centre of gravity falls pretty well between the feet, and not in a lopsided manner away over one foot with a steady tendency to get worse. With this last type the *practitioner of experience may make some sort of a patch-work.* For the purposes of this discussion they are of no interest to us, for if our modern movement towards finding our physical defectives early by properly staffed orthopaedic clinics grows and succeeds, few cases will ever be allowed to pass into this stage in another generation.

The orthopaedic surgeon of the next generation must prevent the third stage from occurring, except in rare cases. For example, tuberculous disease of bone and joint to-day is not allowed to produce the gross deformities which occurred when I was a student. In many areas public opinion has been so educated that the mothers of the village will insist that every lame child must go to the orthopaedic clinic which is to be found in the nearest *market town. That point* has been already proved in the county of Shropshire. Dame Agnes Hunt has seen to it that in that county no new preventable deformity shall occur.

Reverting to the second group of cases—those in which the surgeon can, by the use of external force and control, produce a correction of the deformity of the trunk as a whole. Three essential factors must, I believe, be recognized and acted on.

1. That in the *thoracic region* rotation deformity is the dominant difficulty to be overcome; and that Hoke has shown that the ribs are a lever rotating the vertebrae. This factor of deformity can be corrected by training in breathing, which can be reinforced, if need be, by suitable splinting.

2. That in the lumbar region correcting the lordosis helps materially to correct the lateral deformity and indirectly corrects the rotation. In this connexion extending the pelvis on one thigh exercises a correcting influence on the lumbar twist, and this correction can be obtained even in the sitting position. The flexed plaster jacket compels the patient to exercise the extension of the hip-joint for postural purposes, and therefore secures this action, as is done in an Abbott's jacket.

3. Deviation of the body weight on to the foot which the patient is not in the habit of using, taken either as a system of training or as part of posturing by jackets, alters the whole postural reflex habits of the patient and helps to correct the deformities, if properly applied. This is the foundation of Haglund's jacket.

Finally, gymnastic treatment serves only two purposes: (a) To loosen joints—that is, to increase the range of inhibition and movement of muscles. All ordinary movements in the gymnasium contribute to this. Such exercises are not corrective, but only preparatory. (b) To re-educate the patient in habitual posture so that the postural reflexes which are automatically used by the patient in ordinary life shall tend to correct, not to perpetuate, the deformity. This training must be done outside the gymnasium by the patient's own will power. For this reason I have never allowed myself to run a gymnasium for curative exercises. Also in my practice these exercises are entirely devoid of arm and leg wagging; they consist of correct balancing and breathing when lying, sitting, or standing, and can be practised habitually on ordinary school or nursery furniture, in buses or trains, and walking down the street without doing anything conspicuous.

This training is entirely psychological, and I hold it as a matter of prime importance that the patient should *have all ideas connected* with corrected breathing and posture associated with the ordinary occupations of life, not with some gymnasium or other. For this reason I hold that the gymnast must train the patient in her own home surroundings to get the best results.

My best results have not been obtained in hospital patients; the psychological environment of the ordinary life of the patient is not conducive to the highest form of success.

To conclude. *I would suggest* that more attention should be paid to rotation deformity, that apparent deviation of the spines of the vertebrae be almost disregarded, for this deformity is often deceptive and never an accurate measure of the real distortion.

Lastly, do we treat our cases with sufficiently powerful means of correction in the early stages?

THE TRAINING OF THE GYNAECOLOGIST.*

BY

THOMAS S. CULLEN, M.D.,

PROFESSOR OF CLINICAL GYNAECOLOGY, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

WHEN a physician's labours are confined largely to one sphere of activity he is often prone to think that his is the only field worth while. It is essential for him to mingle frequently with his colleagues of other branches. For years it has been my good fortune to be associated with that master gynaecologist Howard A. Kelly, and to him I owe an eternal debt of gratitude. Over a period of ten years I made frequent visits to a hospital in a remote part of the State of Maryland. Here I found many poor people who needed urgent attention, and in this small institution it became incumbent on me to do all kinds of surgery. I believe that it was this experience that did more than anything else to convince me that every gynaecologist must be an abdominal surgeon. In other words, when he opens an abdomen he must be prepared to deal with any condition that he may find, whether or not it be gynaecological in the strict sense.

One practitioner may prefer to do stomach and gall-bladder surgery, and another pelvic surgery in the female, but when either has an abdomen open it is only fair to the patient that every lesion found in that abdomen be treated at the time if it be humanly possible. It is no excuse for one to say that the lesion is out of his line, or that he is not capable of doing the operation, and then close the abdomen. In the short time at my disposal I shall attempt to amplify this viewpoint.

Naturally a fundamental knowledge of medicine is absolutely essential. In the next place, every surgeon, if he is to get the most out of his work, must have a thorough grounding in general pathology, and also in the surgical pathology of the particular branch which is to become his life-work.

Let me state the method of training that the men who are going to be gynaecologists receive at the Johns Hopkins Hospital. Each year five of the graduating class are

* Read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Manchester, 1929.

assigned to the gynaecological department. During the year these men have charge of the patients in private and public wards, take all the histories, assist at operations, and work in the gynaecological and cystoscopic dispensaries. At the end of the year, after a conference with the house staff and the visiting staff, one of the five men is selected for promotion. The other four obtain hospital appointments elsewhere or enter private practice.

The man who has been selected now drops out of the gynaecological department for a year and becomes an assistant of Dr. William G. MacCallum, professor of pathology. During his intern year this man has obtained a very good idea of the difficulties encountered in the various abdominal and pelvic operations, and consequently is better able to appreciate the opportunities afforded him in the pathological department. He is, however, no novice in this laboratory, because in his undergraduate days he received his instruction here. He is now permitted to make numerous necropsies and gains a clear idea of gross pathological lesions. While making the necropsies he has the opportunity of dissecting out the ureters and of learning the relations of the pelvic structures. He is continually dissecting out the bile ducts to see if they are patent, and has ample opportunity to observe the lymphatic ducts carefully. He also gains a lasting knowledge of the relations of the abdominal organs and of the blood supply. After a year's opportunity in such work he should never again get lost in the abdomen. In addition to all this he gains an insight into the lesions in all parts of the body, and has the opportunity of studying the various histological pictures presented at necropsy. He likewise has the privilege of attending again the undergraduate classes in pathology, and of participating in the invaluable pathological conferences that are held each week.

At the end of a year our assistant in pathology returns to the gynaecological department; he examines and describes all material coming from the gynaecological operating room, supervises the cutting and staining of sections, and gives a detailed and careful description of the histological findings. Ample time is afforded him to work on special gynaecological problems, and he is within easy distance of that mine of information the Surgeon-General's Library, where practically every medical book and periodical that is worth reading can be obtained. He also has an opportunity to see all the interesting cases treated in the department. During the following year he is first assistant, assists at operations, has general supervision of the wards, and when the resident is away is in charge. During his final and fifth year he is the resident gynaecologist and has full charge of the department, and, in addition to assisting the visiting surgeons, performs many major and minor operations himself.

The finished product is: (1) A man who has a good knowledge of general pathology and an intensive knowledge of gynaecological pathology. (2) A man with a comprehensive knowledge of gynaecological and abdominal diseases. (3) An expert gynaecological and *abdominal* surgeon. (4) A surgeon who has formed the habit of looking at his cases from every viewpoint.

A man with such a training will not only do justice to his patients, but should also prove an admirable teacher. He is bound to add to the sum total of our knowledge of gynaecology and abdominal surgery. Few men who have become real investigators will ever be satisfied to relinquish this fascinating field during their active period of surgical life.

Every gynaecologist and general surgeon has a group of cases that worry him greatly. Some of these patients have had pelvic operations, others have had their appendices or gall-bladders removed and still are far from well. They have pains in the right or left lower abdomen or on both sides; occasionally they have discomfort in the renal region, and often they complain of frequent urination. The urine itself may contain an occasional pus cell or be practically normal. This group of cases has given the conscientious surgeon untold anxiety, and he has often been at his wits' end to determine just what is the matter and what he should or should not do for them.

In recent years my colleague and friend Guy L. Hunner, associate professor of gynaecology in the Johns Hopkins Medical School, has pointed out that many of these patients have unilateral or bilateral ureteral strictures, and that by dilating these strictures the patients are relieved of their symptoms and again become normal individuals. In some of these cases it is necessary to re-dilate the ureters from time to time, just as one must do when strictures exist elsewhere. Hunner's epoch-making labours are receiving more and more attention the world over, and before long his methods of treating ureteral stricture will be employed everywhere.

Here I should like to say that while in the male urology is logically a distinct specialty, in the female bladder and ureteral lesions are so intimately associated with pelvic infections and pelvic tumours that it is essential that the gynaecologist of the future be a good urologist. As we all know, the diagnosis of pelvic lesions is often very obscure, and it is frequently impossible to forecast just what one will find when the abdomen is opened. For the benefit of those who are general practitioners—the backbone of the medical profession—I shall mention a few cases illustrating these difficulties.

I often tell my students that the abdominal cavity suggests to me a long, partially collapsed silk balloon moulded to the various abdominal structures and covering over the inner abdominal walls. This simile is of surgical importance; for example, suppose that we have a case shortly after labour in which there is thickening in the right lower abdomen, and the diagnosis lies between broad ligament induration and an acute appendicitis. If it be an acute appendicitis the abdomen should be opened at once and the appendix removed. If, on the other hand, the thickening be due to broad ligament induration, in no circumstances should the balloon be opened. All that is necessary in this case is to make a gridiron incision as for an appendix, and when the peritoneum is exposed to push it gently inward until the area of thickening in the broad ligament is reached and a drain can be laid down to this area. The induration usually softens up in a few days, and as the abdominal cavity has not been opened there is little or no danger of a streptococcus peritonitis.

On one occasion, while in the country, I saw a patient with what appeared to be an adherent myoma of the posterior surface of the uterus. Not being absolutely sure of the diagnosis I did not operate on her at the local hospital, but brought her to Baltimore. On opening the abdomen we found diverticulitis of the sigmoid low in the pelvis and a small abscess in Douglas's cul-de-sac. Because of the extensive inflammatory thickening, it was thought wise to do a resection notwithstanding the abscess. Fortunately the patient made a good recovery.

Recently I saw a patient with a multinodular myomatous uterus filling the pelvis and extending halfway to the umbilicus. She had pain of short duration in the right lower abdomen. Was the condition a pus tube or an acute appendicitis associated with the myoma? If a pus tube, we could perform hysterectomy and remove the pus tube at the same time: if an acute appendicitis with abscess formation, it would be fatal to attempt hysterectomy at that time. We made a gridiron incision and found an appendix abscess. The appendix was removed and the abscess drained. The hysterectomy will be done four or five months later.

During the last few years I have seen several cases in which an acute appendicitis complicated a pelvic tumour, and in each case only the appendical trouble was treated, the tumour being removed later.

Now let me refer briefly to a few cases in which the pelvic surgeon must go far afield. We have a large myomatous uterus that has persisted for years. A loop of bowel is so firmly adherent that it cannot be saved. In addition to the hysterectomy an extensive bowel resection is necessary.

I have already recorded a case in which a large myoma almost filled the abdomen. Its upper part had suppurated, grown fast to, and opened into the transverse colon. The uterus was amputated at the cervix, completely freed from the broad ligaments, the cervix closed, and the pelvic toilet completed. The pelvis was then filled with gauze and the myoma and transverse colon lifted out of the abdomen, carefully walled off, and the diseased portion of the

transverse colon removed with the myoma. During the entire operation not a drop of pus escaped.

One Sunday afternoon a coloured woman was brought to the hospital as an emergency. The pelvis was choked with a myoma. As soon as this had been removed we found a carcinoma of the sigmoid. For this a resection of the bowel was necessary.

A frail little woman, 58 years of age, for years had been carrying about a very large abdominal tumour. It finally gave rise to so much dyspnoea that operation was imperative. When she went on the operating table she weighed 174 lb.; when she was returned to her room her weight was 85 lb., and by the time the oedema had left her extremities her weight was 80½ lb. The tumour, a cystic myoma, weighed 89 lb. It was attached to the uterus by a pedicle no thicker that one's finger. The myriads of blood vessels going to it had been supplied by the omentum, stomach, and liver. It was necessary to remove a piece of liver with the tumour. This patient lived to be nearly 80.

A patient had had a previous operation in a neighbouring State. She had two faecal fistulae in the abdominal scar, and in the pelvis a globular mass, about 10 cm. in diameter, that felt like a myoma. An elliptical abdominal incision was made embracing both fistulous openings. In the abdominal cavity the intestines were more tied up and twisted than any skein of wool could possibly be. I could follow a loop for a short distance; it would gradually contract. It communicated with the pelvic tumour by a fine opening. Nearly all loops that I picked up ended in the same manner. It was absolutely impossible to unravel the tangle. Finally, remembering that the bowel and mesentery may be likened to a fan, the roots of the mesentery being the handle and the bowel the fringe to the fan, I went down to the mesentery, traced it up to a normal-looking loop of bowel, and clamped the bowel at this point. Going back to the mesentery, I traced it up to another normal loop at a distant point and clamped. All the intervening bowel was now cut away, the ends closed, and a lateral anastomosis done. Even in the laboratory it took a long time to get one's bearings. The supposed myoma was a faecal cloaca into which many loops opened. The patient made a prompt recovery.

In a neighbouring town I saw a frail woman with a pelvic and lower abdominal tumour. As it was evident that she would need unusual post-operative care, I brought her to the Johns Hopkins Hospital instead of operating at the local hospital. On opening the abdomen I found a carcinoma of the descending colon. This had eaten its way into a loop of small bowel, and the carcinoma had plastered itself against the posterior surface of the uterus. The appendix was also adherent to the tumour. The case seemed desperate, but the family physician urged operation, saying she could not live ten days without it. A supravaginal hysterectomy was done, both tubes and ovaries being freed with the uterus. The pelvic toilet was completed, and the pelvis filled with gauze. The appendix was freed from the caecum and covered over so that it could not infect the operative field. The involved bowel and the pelvic structures were now lifted out of the abdomen and carefully walled off. A large portion of the descending colon and the involved loop of small bowel were clamped and cut off, the portion of large bowel, the loop of small bowel, the appendix, the uterus, tubes, and ovaries being removed in one piece. The four ends of bowel were closed and two lateral anastomoses made. The patient made a slow recovery and lived in comfort for about a year and a half. She then died suddenly.

I have cited these cases to give you some idea of the extensive and alarming conditions with which the gynaecologist is now and then confronted. I need not elaborate on the frequency with which chronic appendicitis and gall-bladder conditions are associated with pelvic lesions.

From the foregoing it is clear that any man attempting to do abdominal surgery must be master of the situation, if such a thing be possible. Every man going into gynaecology must have a thorough training in the surgery of all parts of the abdomen. The supreme test is: What man would you select to do an abdominal operation on one of your own loved ones? The answer is: The man who can treat any lesion he finds in that abdomen. This being the case, we are in duty bound to so train our young gynaecologists that they will be capable of handling any abdominal emergency that may arise, if that be surgically possible.

In short, I confidently predict that in the very near future no surgeon, except in the rarest emergency, will be accorded the right to open any abdomen unless he has been trained to handle any and all complications he may find in that abdomen. This applies to your country and to mine, and to all other countries where abdominal surgery has reached the high standard of to-day—a standard of which the medical profession of the world is so justly proud: a standard made possible through Louis Pasteur and our beloved and revered Lord Lister.

TOXIC ABSORPTION DUE TO FOCAL SEPTIC LESIONS:

*ITS EFFECTS ON THE PRODUCTION OF EYE DISEASES.**

BY

A. F. MacCALLAN, C.B.E., M.D.Cantab., F.R.C.S.,

ASSISTANT OPHTHALMIC SURGEON, WESTMINSTER HOSPITAL; ASSISTANT SURGEON, ROYAL EYE HOSPITAL.

A well-known English writer, in an interesting article in one of the Sunday papers of April 28th last, described the superior skill of an ophthalmologist practising in a certain Continental town. The theme of the article was that British ophthalmologists think of nothing but ordering glasses, while the Continental surgeons investigate the patient's condition and cure it by treatment. In the opening papers and discussions at this Section on the selected subject, it will be evident that British ophthalmology is leading in the investigation and treatment of certain eye diseases, which in some other countries are looked upon as of unknown origin, or as dependent on some obscure constitutional condition.

As the article to which I have referred above has had a very large circulation, and will result undoubtedly in material benefits to the inhabitants of the town mentioned in it, I should like it to be known that not all cases treated in that town have such happy results. At the time of writing this paper I have under my care in the ordinary wards of Westminster Hospital a poor lady who has spent her small means in obtaining treatment for cataract at that town. The patient had received no benefit from her treatment abroad, nor was it likely that she would do so. As she was no longer able to walk about, I extracted her immature cataracts, to her great joy.

The subject which has been chosen for discussion is very important, and one in which I have taken great interest, especially during the last two years. Reports of clinical researches by me will be found in the *Transactions* of the Ophthalmological Society of the United Kingdom for 1928, and in the *Proceedings* of the Royal Society of Medicine, *Section of Ophthalmology*, 1928. Also an article by me on "The relationship between dental and ocular disease" appeared in the *Dental Journal* in 1928. Due acknowledgement was paid in them to the personal teaching of William Lang, and to his opening address on this subject at the Oxford Ophthalmological Congress of 1923.

Nature of the Products of a Focus of Sepsis, and the Channel whereby these Products reach the Eye.

The exciting agent of ocular changes must be living or dead bacteria, or the toxic products of bacteria, or the disintegration products which result from the action of bacteria on the body cells. In extraocular inflammations of the conjunctiva and eyelids, as well as in orbital cellulitis, it may be a bacterial infection which spreads by contiguity of tissue, or by way of the nose and lacrymal passage. In intraocular changes it is either the toxins of the bacteria or the disintegration products which are the exciting agents; their path to the eye must be by the

* A paper read in opening a discussion in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Manchester, 1929.

general blood stream—that is, they pass to the heart, thence to the lungs, back to the heart, and thence by way of the aorta and carotid arteries to the orbit and globe. In some cases of orbital cellulitis there is no doubt that bacteria spread to the orbit by the blood stream.

Sites of Foci of Sepsis, and Similarity of Effects, wherever the Focus may be.

In adults the most usual site of focal sepsis is the mouth, while in children it is the tonsils. With less frequency, in my experience, the site may be found in the intestinal canal, especially in the appendix, and sometimes in the colon or duodenum. The gall-bladder in either sex, and the pelvic organs in the female, may contain the exciting cause. After gonococcal infection in the male the deep urethra and the vesiculae seminales often contain a mixed growth of various organisms, which may lead to a general toxaemia and localization of inflammatory changes in the eye. I have seen ocular changes result from a chronic inflammation in the stump of a leg amputated for a war injury. In fact, any chronic focus of sepsis may set up ocular changes.

It may be a difficult or impossible task to decide on the position of a focus of sepsis in a case of ocular change which has every appearance of being produced by this condition. Nevertheless it is the obvious duty of an ophthalmic surgeon who recognizes such a case either to look for the focus himself or to obtain the assistance of some medical man who will do it for him, and who is competent to carry out the investigation.

A distinguished foreign ophthalmologist recently sent to me a reprint of a paper he had written in which he stated that he had never seen any condition of ocular disease dependent on dental sepsis. I am in complete disagreement with this view. I have shown elsewhere, by a detailed description of clinical cases, that dental sepsis is the most common cause of ocular changes, and I have indicated how such a case should be approached. To send a patient, in whom for ocular reasons focal sepsis is suspected, to a dentist who will give an opinion without obtaining really good radiographs of the whole mouth, is frequently to obscure the investigation. In all such cases all teeth and edentulous areas should be radiographed, and we should obtain the opinion of a dental surgeon, who will make a thorough clinical examination of the mouth after studying the radiographs and a report on the ocular condition.

Among the more important indications for the need of expert dental advice are the following conditions.

1. Pyorrhoea, recognized either by the red or inflamed margin of the gums or by the oozing of pus from between the gum and the necks of the teeth. Pyorrhoea, of course, is not a mere gingival inflammation which can be removed by antiseptic lotions, but is the symptom of inflammation of the periodontal membrane. It is a very serious condition, for when of marked degree there is no known method of curing it except by removing the affected teeth and treating the tooth-sockets. Dry pyorrhoea is also a clinical entity. At the Odontological Section of the Royal Society of Medicine, in 1914, Sir Thomas Horder gave an illuminating description of a case of pyorrhoea:

> "In the routine examination of a patient's mouth, the other day, I uttered a mild warning as to persistence in a thorough toilet of the teeth, giving the advice almost casually, because the degree of mischief present was small. To my surprise the patient became quite excited, and began to protest that, whatever else was amiss, it was quite impossible *he could* have anything wrong with his teeth. Urged for a definite reply to this challenge, I examined carefully again, and was quite sure of the presence of pyorrhoea. Whereupon the cause of the excitement came to light in the form of the announcement that *the* authority *on* the treatment of pyorrhoea had, only the day before, declared that a long course of treatment might now be considered at an end, *seeing* that the mouth was quite free from the disease. Nothing could satisfy the patient except the opinions of two independent dental surgeons, both of whom, unfortunately for the patient's belief in human nature, found undoubted pyorrhoea present."

2. Apical abscesses are a more frequent cause of ocular change even than pyorrhoea. The term "apical abscess" is a bad one because pus is not always obvious, and especially because there is no pain. When a tooth with an apical lesion is extracted a mass of solid granulation tissue is found adherent to the apex, which contains pathogenic streptococci and necrotic substances with very few leucocytes. From these apical abscesses there is a constant flow into the blood stream of either virulent streptococci or their toxins, and the anatomical position of the lesions prevents an adequate supply to the part of leucocytes and bactericidal body fluids. When it is remembered that with each bite of the jaw, which has an average pressure of seventy pounds to the square inch, bacteria and their products are pumped into the circulation, it cannot be wondered at that so many ocular and general diseases are rightly attributed to the teeth.

The frequency of the occurrence of apical abscesses is not yet realized by the medical profession. I have only recently appreciated this frequency after studying statistics of my private patients. The reason that the clinical material was taken from private patients was that among hospital patients gross oral sepsis is generally recognized to be the rule rather than the exception. I took two consecutive series of patients, the first of 100, and the second of 50 persons. Of the first series 52 per cent. were under 40 years of age, and of the second series 46 per cent. All the patients had full vision in each eye with glasses, all other patients with less acuity of vision being omitted from both series. The majority of the patients belonged to the upper middle class and were quite able to obtain skilled dental attention, which indeed most of them had had. In the first series 22 per cent. were found to have radiographic evidence of one or more apical abscesses, and in the second series 10 per cent. In most cases this was verified by extraction, which is, of course, the only treatment for the condition. However, one titled and wealthy lady, who had five teeth certainly affected with abscesses, as well as two others in which there were apical changes, possibly due to abscesses, refused to consult either any family doctor or dentist about her condition. She had no pain and I suppose her blood resistance was good. I may mention that she also had proptosis of one eye, for which radiography of the skull and sinuses revealed no cause.

3. The septic stumps of teeth which have been broken off about level with the gums frequently have an abscess at their roots. This condition, while very common among hospital patients, I have also found among 10 per cent. of my private patients.

4. Buried fragments of previously extracted teeth very frequently give rise to toxic absorption. They result from difficult extractions, but should, of course, be immediately recognized as left by the dental surgeon, who should carefully examine the apex of every tooth removed to see that it is entire. Should an apex be left, and should it be impossible for it to be at once removed, it ought to be extracted at a subsequent operation; 4 or 5 per cent. of my private patients were found to have buried fragments present, although all of them were under regular examination by reputable dental surgeons.

5. Unerupted impacted teeth were found by radiographic means in 5 patients out of 33 who were radiographed in my above-mentioned series of 100 cases. The impacted teeth were usually the third molars, sometimes the upper canines. In *The Dental Cosmos* for May, 1929, Ito has shown that in 8 out of 10 cases in which impacted third molars were extracted with aseptic precautions a growth of *Streptococcus viridans* or *pyogenes* was obtained from cultures from the pulp chamber.

It may be taken, therefore, that all impacted teeth are infected. Certainly every case which I have examined has shown evidences of ocular infection. Unfortunately the removal of an impacted tooth is a serious operation, and can only be undertaken by a specially skilled oral or dental surgeon.

6. Residual sepsis or bone infection may be indicated in a dental radiograph and may be confirmed when operation is undertaken to scrape away the diseased area. I have more than once found this condition to be responsible for intractable corneal ulceration.

The above are the more common conditions of dental sepsis which I have found to give rise to ocular changes.

In many cases active ocular inflammation has subsided after dental treatment has been undertaken. I wish it to be particularly noted that in no case of mine have extractions been advised unless a dental surgeon has considered these necessary on purely dental grounds.

Sometimes, and not infrequently, it happens that some ocular change exists which may possibly depend on dental sepsis, but, the patient declaring that he is edentulous, this cause seems impossible. A lady of 32 years of age whom I saw recently in private consultation told me that she suffered from lacrymation. On examination under cycloplegia she was found to be emmetropic, and no ocular disease was found except slight macular hyperaemia. Her only remaining teeth, she told me, were the lower central and lateral incisors. With some hesitation I asked her to remove her upper and lower dentures, when I saw that she had a small septic stump just showing in her upper jaw. This was evidently the cause of the condition, as after the removal of the stump her lacrymation was cured without ophthalmic treatment. In other edentulous patients dental sepsis may still be present owing to the presence of buried fragments of previously extracted teeth or owing to residual sepsis of bone.

Far short of the varieties of dental disease which I have mentioned even the accumulation of a very moderate amount of tartar on the teeth may lead to iritis. I saw a patient at the Royal Eye Hospital recently with an attack of iritis in the left eye. After detailed clinical and pathological investigation no local or general condition was found which could account for the inflammation. On the chance of there being some dental complication present which I had not sufficient knowledge to detect, I sent him for examination to Dr. Livingstone of King's College Hospital dental department, who found oral sepsis resulting from deposition of tartar. The patient's teeth were thoroughly scaled, and within a week the inflammation of the iris had subsided.

Although I have laid considerable stress on dental sepsis as associated with eye disease, and in many cases as being the sole cause of the condition, it is by no means the only cause. Gastric and duodenal ulcer, and inflammations of the gall-bladder or appendix may give rise to ocular changes, but these ulcers and inflammations are usually attributed to dental sepsis, which may be active, or which may have been previously present but has been eliminated.

It may be considered that I am speaking at unnecessary length on the dental question, but I am doing so because ophthalmic surgeons usually have little acquaintance with the groundwork of dental science. I had as little acquaintance as any other until the days of my out-patient clinic at Westminster Hospital coincided with those of the dental surgeons, Mr. Bowdler Henry and Mr. Lawrence, who gave me the greatest assistance in examining the teeth of the ophthalmic patients under my care, and in explaining to me some of the elementary facts of dental surgery. I also received great assistance from Dr. Livingstone for my cases from the Royal Eye Hospital.

In children the teeth are only occasionally the cause of ocular changes. But the tonsils are a frequent cause. It does not require great knowledge to note enlargement of the tonsils, though the expert advice of a throat surgeon may be required to decide as to whether or not they are actually septic. It frequently happens that when an operation for removing the tonsils is performed, it is found that they are much more septic than the throat surgeon supposed. It is also within my experience that one surgeon may believe the tonsils to be about normal or perhaps a little enlarged, and that another surgeon will operate and find pus in them.

Focal sepsis centred in the intestinal canal, the female pelvic organs, or the male genital organs is very difficult to eradicate. Time will not allow me to refer to these causes in further detail.

Organic Resistance to Toxic Effects.

At the International Congress of Military Medicine, held in May of the present year in London, a very interesting communication on the state of the teeth in relation to physical fitness in the different military services was read by Surgeon Lieut.-Commander Wood, with Captain S. H. Woods and Lieut.-Colonel Colbran of the Army Dental Corps.

"Our masticating organ is different from any other organ of the body in one respect. It may retain its normal functional efficiency for a very long period concurrently with extensive and injurious pathological changes in its tissues. Pyorrhoea alveolaris, involving all or many of the teeth in a mouth, may be present for years, and may cause widespread constitutional symptoms, but the functional efficiency of the teeth will only be affected by their progressive loosening or tenderness. Again, apically infected teeth may be conserved and rendered fully functional and apparently healthy for many years, yet, as a result of such conservation, there may be constant absorption of toxic products from the infected apical tissues, producing distant systemic lesions.

"The term 'dental sepsis' implies infection of the tissues immediately in contact with the teeth, starting in the periodontal membrane. This membrane is either infected externally, via the gingival trough, or internally, via the apical foramen.

"The external affection of the periodontal membrane produces conditions which we may group as 'open' dental sepsis, for there is communication between the mouth and the infected tissues. Chronic gingivitis and pyorrhoea alveolaris are obvious examples.

"Infection via the apical foramen produces changes of the periapical tissues grouped under the heading 'closed' dental sepsis, as the condition is confined.

"The infection always involves the adjacent alveolus because of the anatomical relationship. The infection is generally a low-grade one, and the organisms are chiefly the *viridans* group of non-haemolytic streptococci.

"The involved tissues are invisible, and the condition may be present for long periods without necessarily causing any local symptoms.

"Once dental sepsis is established in the masticating organ the effects produced on general health will depend on the interrelation of four main factors:

"(1) The virulence of the infective organisms—that is, the intensity of attack.

"(2) The volume of toxins absorbed—that is, the extent of the attack.

"(3) The time-factor—that is, the duration of the attack.

"(4) The resistance of the body—that is, the defence."

The resistance factor is extremely important. Fortunately for those who have devitalized and crowned teeth in their jaws their resistance is often good. From my experience I should say that radiographic examination would show that about 20 per cent. of persons with one or more crowned teeth have one or more apical abscesses. All of these would show ophthalmoscopic changes as the result.

It may, of course, be asserted that the association of severe dental sepsis with unmistakable ocular changes is a coincidence. The reply is that the association is constant. These ocular changes, which will be described later, may be produced by any form of focal sepsis, dental, tonsillar, due to sinusitis, or intestinal, and at present the causative varieties of sepsis cannot be differentiated one from another by the ocular effects.

The Path of Infection from Foci of Sepsis to the Eye.

There are three paths whereby the products of focal sepsis may reach the eye: the first is by direct extension, the second by lymphatic absorption, and the third by deglutition of the products of tonsillar or dental sepsis and their subsequent absorption from the alimentary canal.

1. The effects resulting from direct extension may occur from sepsis situated either in the mouth (in open dental sepsis), tonsils, nasal mucous membrane, or accessory nasal sinuses. The effects produced may be blepharitis, inflammation of the Meibomian glands, including both acute and chronic tarsal cysts, ordinary conjunctivitis, acute and chronic, phlyctenular conjunctivitis, episcleritis, corneal ulcer, dacryocystitis, and orbital cellulitis.

2. The effects resulting from lymphatic absorption occur in closed dental sepsis, chronic tonsillitis, and chronic inflammations in any part of the body. These effects may be those mentioned in the previous paragraph, also iritis, cyclitis, some forms of choroiditis and retinitis, embolism or thrombosis of the central artery of the retina, and thrombosis of the central vein of the retina or of one of its tributaries. I have no doubt that acquired non-traumatic cataract has its inception in focal sepsis.

3. The effects produced by deglutition of septic material and its absorption from the intestinal canal may occur in any inflammation of the mouth, nose, or pharynx. They do not differ from those enumerated in the preceding paragraph.

Ocular Diseases Associated with Focal Sepsis.

Blepharitis of a severe degree is not infrequently associated with enlarged and septic tonsils in children. I have also seen it in a child of 6 years in whom practically all the teeth were carious. In adults it is usually an accompaniment of open or closed dental sepsis. If the causative condition is dealt with, and a little ointment applied to the lids, the condition usually subsides permanently. If there is any marked ametropia it may be corrected. It is, however, in my opinion, a mistake to correct small degrees of ametropia in children who are suffering from blepharitis and leave the causative tonsils untreated.

In the time at my disposal it is impossible for me to narrate details of clinical cases in support of my arguments. I have published elsewhere reports of numerous clinical cases bearing on the subject. I should like, however, to tell you more particularly of one of the most grateful patients I ever had, whom I put in the way of getting cured not only of blepharitis, but of a distressingly poor complexion.

This was a young married lady of 25, who was sent to consult me by a physician on account of severe blepharitis of recent onset. She had glasses for occasional use prescribed by an ophthalmic surgeon, which on careful examination were found to be practically correct. She had slight hyperaemia in the macular regions of both eyes. With the slit-lamp fine dusty clouds were seen with the naked eye in the vitreous, and microscopically opaque fibrils. Dental radiographs were obtained which indicated the probable presence of apical abscesses in upper left 4, and lower left 5, both of which had filled roots. The patient was advised to see her usual dental surgeon, and to submit the radiographs for his opinion. The dentist immediately removed the crowned teeth, and subsequently on his own initiative another dead tooth. I saw the lady recently, when she had no blepharitis, and a natural complexion without any of the spots which had previously spoilt her good looks.

Meibomian cysts are almost invariably associated with dental sepsis, whether in hospital or private patients. The cyst should be dealt with surgically and the dental sepsis eliminated. I recognize no connexion between cysts and errors of refraction, though they frequently coexist.

Several forms of *conjunctivitis* of a chronic variety, including angular conjunctivitis, may be caused by dental or tonsillar sepsis.

Phlyctenular conjunctivitis in children is usually associated with enlargement of the tonsils. When the tonsils have been dealt with surgically, and the child has recovered from the toxaemic condition produced by the absorption of toxic products from the tonsils, the phlyctenules disappear, aided, of course, by appropriate local treatment.

Episcleritis is almost invariably associated with open or closed dental sepsis. If the ocular condition is observed at an early stage, and the dental condition is adequately dealt with, the episcleritis rapidly disappears. On the other hand, if the condition is of long standing it is very intractable, even though the oral cavity is rendered healthy.

Corneal Ulcer.—The treatment of ulceration of the cornea has been immensely improved since I and my assistants realized the frequency with which the condition is associated with focal sepsis. Our experience shows that it is more commonly met with in the out-patient department of a London hospital in people over 30 years of age and more frequently in men than in women. There is usually a history of some slight injury preceding the onset of an inflammatory condition. Examination of the mouth in almost every case shows the obvious presence of some form of open dental sepsis, from which there is a constant flow of pyogenic organisms to the conjunctival sac. Also in these cases there is a great deal of absorption of toxic material by the lymphatics of the mouth, and after deglutition by the lymphatics of the intestine, which renders the cells of the conjunctiva and cornea less able to deal phagocytically with the ordinary flora of the conjunctival sac. These organisms flourish on, in, and between the superficial cells of the conjunctiva, and cause erosion of the bared corneal tissue. It is necessary to arrange for such a patient to obtain skilled dental treatment the same day or within twenty-four hours if the ulceration is to be checked and the local treatment is to be effective. Merely to advise such a patient to seek dental treatment, either privately or at a hospital, without making immediate and adequate arrangements for this to be obtained, is insufficient. At the two hospitals where I carry on ophthalmic clinics I can be sure that most skilled advice will be given either the same day or the next day, and that the dental treatment, whether it is merely the removal of tartar and general cleansing, or whether it entails the extraction of one or more teeth, will be carried out forthwith.

Dendritic ulcer is peculiarly associated with dental sepsis, and is as often met with in private practice as in hospital work. The patient's whole mouth should at once be radiographed in order to determine the extent of the periodontitis if present, and to detect the possible presence of apical abscesses. The patient should then see a dental surgeon without delay, taking the radiographs and a letter from the ophthalmic surgeon explaining the importance of the ocular condition.

Dacryocystitis is usually associated with one or other form of dental sepsis, and is, I believe, frequently caused by this condition. It is not the case, however, that elimination of the dental sepsis results in a cure of the dacryocystitis without surgical intervention.

These conditions which I have just discussed—blepharitis, tarsal cysts, some forms of conjunctivitis, episcleritis, corneal ulcer, and dacryocystitis—are more usually caused after lymphatic absorption of toxic material than by direct extension. A bacterial culture from the conjunctiva rarely shows the same organism as that from the primary focus of sepsis.

Experience has shown that, for practical purposes, it is immaterial what the organism is which is found on the lids or conjunctiva, as the treatment is the same in all cases—that is to say, the immediate elimination of the primo focus, as far as is possible, and frequent irrigation or bathing of the eye with a slightly hypertonic salt solution. It is important that the eye shall not be occluded with a pad and bandage and allowed to stew in its own juice. Of course, if necessary the pupil will be kept dilated.

Iritis may result from either open or closed dental sepsis, from tonsillitis, and from other forms of focal sepsis. I have already mentioned the case of iritis which subsided a few days after tartar had been removed from the teeth. Much more serious inflammation of the iris is sometimes met with, in which the most careful general, physical, and chemical investigation indicates no possible cause except some form of focal sepsis, and when this is eliminated the iritis often subsides in early cases.

Cyclitis, either alone or in combination with iritis, as is well known, may be, and generally is, the result of focal sepsis. It is of the greatest importance to find and eliminate the focus as early as possible, as when the disease has taken a firm hold of the eye, owing to the constant and long-continued action of the toxins, it is difficult or impossible to eradicate. In these cases there may be more than one focus at work. I have two cases under treatment at the present time in which there was definite closed dental sepsis, revealed radiographically, and also severe tonsillar sepsis, according to expert opinion. Therefore, although one focus may have been found, it must not be taken for granted that it is the only one present in the body, nor the only one producing toxic conditions.

It may be, however, that although there are several foci of sepsis present, only one of them is actively harmful.

In one of the cases of cyclitis I have just mentioned I obtained the opinion of a throat surgeon, who said that the tonsils were enlarged and septic, and in his opinion they should be enucleated. Radiographs showed a well-defined apical abscess under the left lower second, and an unerupted impacted right lower third molar. The dental surgeon, to whom I sent the patient with the radiograph and my ophthalmic report, agreed with the probability of there being an apical abscess, and said that there were two others which were dead, which, in view of the patient's ocular condition, would be better out. As regards the impacted molar, he stated that the radiographic appearance was that the bone around the tooth was infected, and that an operation should be carried out for its removal. The patient, with my sanction, took the opinion of a general surgeon on the advice he had received, which was that it was very advisable that the affected and dead teeth should be removed, and that the tonsils should be enucleated. However, the patient, a city merchant, pleaded the importance of his private affairs, and merely consented to have the abscessed tooth removed under local anaesthesia. A few days after the operation the deposits on the back of the cornea increased considerably; a week later they had diminished so much as only just to be visible to the naked eye; while after three weeks had elapsed the condition was apparently cured.

In this case it appears that, although several sources of sepsis were present, we hit on that causative of the ocular condition, and eliminated it with happy results.

Any discussion as to the relationship of certain forms of choroiditis and retinitis, of embolism or thrombosis of the central artery of the retina, and of thrombosis of the central vein or of its tributaries to various forms of focal sepsis, I must leave to others. I have seen examples of each of the above-mentioned conditions during the past year, and in each of them a fulminating focus was present in the body which in my opinion bore an etiological relationship to the ocular condition. As there is no known means of influencing such embolism or thrombosis, it is clear that elimination of the focus, which was undertaken whenever possible, could not prove the relationship by curing the condition.

Hyperaemia of the retina at the macula, unaccompanied by other fundus changes, is very frequently found to be present in conditions in which toxic products are being poured into the circulation. It is usually accompanied by changes in the vitreous, and sometimes by changes in the lens. If the toxaemia continues, pigmentary changes or definite degeneration occurs. It is remarkable that some patients with very obvious degenerative changes at the macula retain full visual acuity.

Changes in the vitreous invariably accompany any long-continued focal sepsis. The normal vitreous in children who are completely healthy and who have never suffered from tonsillar sepsis has no opacity to be seen by the slit-lamp, except vestigial filaments. The change due to sepsis is a naked-eye floating film, while microscopically a trabecular structure can be made out. This condition is stated in the books on slit-lamp microscopy to be normal; however, I believe it to be pathological.

Cataract is the term applied to any opacity of the lens or its capsule. Such opacity may be congenital, acquired, or traumatic; the present remarks apply only to the acquired variety. The frequency of cataract is not fully appreciated. I have published two series of cases which show that 33 per cent. of patients drawn from the upper and middle classes have opacities in the lens, as seen by ordinary focal illumination, while an additional 12 per cent. exhibit opacity when the slit-lamp is used. These series were composed of patients of whom 50 per cent. were under 40 years of age. In practically all these patients an obvious focus of sepsis was found.

In all the complete cataracts that I have examined during the last few years in hospital practice there has been either actually present or previously present a definite focus of sepsis, more often situated in the mouth than elsewhere. In the forthcoming volume of the *Westminster Hospital Reports* I have written an article on my views of cataract formation, which it is impossible even to summarize here. I may say, however, that it has been shown experimentally that certain toxic conditions can give rise to cataract. Modern ophthalmic literature states that changes in the lens are the result of the action of various toxic substances, produced by the body, on the ciliary processes, resulting in changes in the composition of the aqueous, which in turn injures the epithelium of the anterior capsule of the lens, allowing the entrance of substances which cause cataract.

I believe that the most important cause of cataract formation is the presence of long-continued focal sepsis, generally dental. Therefore it appears to me to be of the greatest importance to recognize in our patients as early as possible the slightest opacity in the peripheral cortex of the lens, to deduce from it the probable presence of a septic focus, to localize the focus, and to put the patient in the way of getting the focus eliminated.

If this was generally carried out very few cataracts would be available for operation in another ten or twenty years' time. However, as long as the ordinary well-to-do person insists on retaining septic teeth in his head, dentists will be found to patch them up and crown them, and we operating ophthalmic surgeons will still have a future before us.

On the day of writing this (May 21st) I saw at Westminster Hospital a girl, 17 years of age, with marked peripheral opacities of both lenses, which would have been called typically senile had the patient been thirty years older. It was what is known as a coronary cataract. The vision with correction for a small degree of myopic astigmatism was fully normal. On inquiring into her history she said that she had never had sore throat, but had had one or two teeth removed which had been defective. On examining her throat she was seen to have obviously enlarged and septic tonsils, for which surgical treatment was advised. In this case the lenticular changes, which would not have been discovered unless the pupils had been dilated with homatropine, may have resulted from septic absorption either from previous dental sepsis, or more probably from the existing tonsillar sepsis. These coronary cataracts cannot be mistaken for congenital opacities, situated as they are in the cortex of the lens.

Primary glaucoma, both acute and chronic, has been stated by Lang to owe its origin to focal sepsis in many cases. In all the cases of primary glaucoma which I have seen during the last few years I have not seen one in which there was not a fulminating focus of sepsis.

Progressive myopia in children, in my experience, is always associated with enlarged and septic tonsils. It seems to me that the whole weight of the ophthalmic surgeon should be thrown in favour of early enucleation of the tonsils if they are not healthy, whether or not the fibroblasts of the sclerotic have already begun to yield to the normal intraocular pressure, as the result of their weakening by the absorption of toxic products.

The effect of focal sepsis on intraocular operations is very marked. This is true of children with septic tonsils who have to be operated on for congenital or lamellar cataract, or for adults with dental sepsis who require operation for cataract or glaucoma. In all cases of adults, when time permits, a thorough scaling of the teeth should be carried out before any of the teeth are extracted, and an interval allowed to elapse before the intraocular operation is done. If there is not time for this the ophthalmic surgeon can, in a somewhat amateur fashion, diminish the danger by the daily application of tincture of iodine to the gums and necks of the teeth, after thorough scrubbing with brush and powder.

Conclusion.

In concluding I realize that I have been unable to deal with this subject fully or adequately. However, such opinions as I have expressed are based on personal experience. At the hospitals where I and my assistants carry on our clinical work during four days each week, it is open to any ophthalmic surgeon to see what is being done, and to note the results we obtain from an acute appreciation of the dangers of focal sepsis.

EPIDERMAL INFECTIONS WITH YEAST-LIKE ORGANISMS;

With Special Reference to Seborrhoeic Eczema.*

BY

G. B. DOWLING, M.D., M.R.C.P.,

DERMATOLOGIST, WEST LONDON HOSPITAL; ASSISTANT PHYSICIAN, SKIN DEPARTMENT, GUY'S HOSPITAL, AND ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

Knowledge concerning the group of epidermomycoses occurring in England, and, generally speaking, northern and temperate climates, caused by organisms resembling yeasts has grown enormously during the past ten to fifteen years. It is a group that has emerged from a heterodox assortment of dermatoses formerly named according to their chief objective symptoms—for example, intertriginous eczema, onychia, paronychia, etc. There followed a period during which it became known that in certain cases these dermatoses were caused by fungi—other, of course, than ringworm; but, generally speaking, the fungi were not precisely classified and were described generally as saccharomyces, or yeasts.

* A paper read in the Section of Dermatology at the Annual Meeting of the British Medical Association, Manchester, 1929

Nowadays, although the botanical position of these organisms is still obscure, *their morphology and biochemical characters* have been the subject of important studies by mycologists. The whole subject is, of course, vast and complex, and could not in any circumstances be presented by me in all its bearings. My object will be to attempt a *brief outline* of the facts regarding the epidermomycoses as they appear to me to concern the clinician especially. I will then attempt to bring another great group of common dermatoses into line with them.

The epidermomycoses are caused by one family of organisms only, known as the Oösporaceae. Although resembling yeasts morphologically, in that they are mainly round or oval bodies which multiply predominantly by budding, and biologically in that some of them ferment sugar, they really belong to a lower order of fungi than yeasts, inasmuch as their mode of reproduction is of the simplest order, ascospore and even endospore formation being unknown among them. They are, therefore, fungi *imperfecti* or *hyphomycetes*. They are classified by Castellani in the following way.

They belong to the order Thallosporales—that is, reproduction takes place by adaptation of the thallus or vegetative body to the purpose of reproduction. This order is again subdivided into the suborders Blasto-sporineae and Arthro-sporineae, to the former of which the yeast-like fungi belong. The characteristic feature of this suborder is that *reproduction takes place predominantly by budding*. The Blasto-sporineae are again divided into families of which two, Cryptococtaceae and Oösporaceae, contain the various genera concerned. Thus the family Cryptococcaceae contains the genera cryptococcus, torula, and, according to Castellani, *pityrosporon*. The chief characteristic of these genera is that they never form mycelium. The Oösporaceae possess genera in which mycelium is present either in the tissues or in culture. Oöspora, oïdia, and monilia belong to this family. According to some authorities this subdivision is artificial and unnatural, for it is well established that the morphology and even the biochemical characteristics of the fungi imperfecti may *undergo certain changes under different conditions* of growth, both as parasites and in culture. A fungus which might, for example, in certain conditions be classed as monilia might appear, under other conditions, as a cryptococcus, or vice versa.

The yeast-like organisms responsible for the epidermomycoses belong chiefly to the genus monilia, of which the definition given by Castellani is as follows: They are Oösporaceae *possessing budding and mycelial forms in situ*, the latter often being long and branched, and in culture mainly budding forms. Dextrose and other carbohydrates are fermented with the production of gas. The most important species is the thrush fungus, *Monilia albicans*, but there are many known species which have been differentiated from one another by biochemical tests.

In clinical practice *examination of scales taken from a* monilia infection generally shows very long, thin mycelium, with occasional lateral thallospores and grape-like clusters of spores arranged lateral to the mycelium. It is not possible to distinguish between one species and another without making biochemical tests. As parasites, the fungi grow best on moist intertriginous surfaces, and the dermatoses caused by them are found chiefly in the natural folds—principally the inguino-crural, intergluteal, submammary, interdigital, and the nail folds. They may also attack the general surface when warmth and moisture are artificially provided, as in continuous water-bath therapy, or as an extension of an intertriginous monilia infection, or when the necessary conditions are naturally provided—for example, by the combination of warm weather and hyperidrosis, certain cases of dysidrosis, for instance, being caused by monilia. The nails may also be attacked.

Space will not permit me to attempt a chronological statement of the earlier recorded cases of monilia infection, and, in any case, this task has already been very well performed by others. Shelmire, for example, made an excellent summary of the subject in 1925, with a complete bibliography. In his paper he refers to all monilia infections as thrush infections. He draws attention to *six main types of infection*: (1) generalized cases occurring in those subjected to continuous water-bath therapy; (2) cases occurring in nursing infants; (3) intertriginous cases; (4) paronychia; (5) infections of the nails; (6) dysidrosiform eruptions. The continuous water-bath cases are known especially in Vienna. The primary efflorescence is composed of dark red infiltrated papules, which become confluent and form areas of polycyclic appearance. As in all cases of monilia infection, the site of maximum growth of the fungus (in this case the border) is marked by a whitish epithelial accumulation.

Thrush infection in nursing infants is not very uncommon. As R. Craik points out, the thrush fungus is a fairly common inhabitant of the alimentary canal of infants. The lesions occur primarily round the anus and in the inguino-crural region in the form of intertrigo, and sometimes spread to other folds, notably the neck; the lesions, as in other cases of monilia infection, consist of erythemato-squamous spots and patches, which become confluent with others. Some of them may be vesicular or pustular. An extensive fatal case has been described by Schamberg. The mother of the infant in this case also had thrush infection of the nipples.

Intertriginous monilia infections are not at all uncommon and are now well recognized. Whitfield reported one of the earliest cases in 1908, describing the fungus as yeast-like. In 1914 cases were recorded by Gougerot and Gaveia, and Hudelo and Montlaur. They recognized the causal fungus as being closely related to thrush. The folds principally attacked are the intergluteal, inguino-crural, submammary, and interdigital. The characteristic features are: whitish and sodden epithelial accumulation at the bottom of the affected fold with an outlying erythemato-squamous eruption, beyond which isolated scaly spots, vesicles, and pustules are usually found. Generally speaking, they lack the sharp outline of epidermophyton infections, and the actual fold is more attacked than in the latter disease. In some cases, however—for example, one described by Engman—no clinical distinction can be made. I had recently a very typical case, in which the patient, in addition, had suffered from seborrhoeic dermatitis for several years. The fungus was easily found in the scales from the erythemato-squamous spots, and epithelial accumulation in the fold by the ordinary method of examining in liquor potassae.

A special type, of which the clinical picture is well recognized, is the erosio interdigitalis blastomycetica of Fabry. The third interdigital space is usually attacked first. The lesion has a sharp margin and is covered with sodden macerated epidermis, which may be detached to display an underlying reddened base. It occurs chiefly among those who have to do wet household work and who have hyperidrosis. When it occurs on the toes it is difficult to distinguish it from interdigital epidermophytosis. In a case of my own the fungus was cultivated in the laboratory at St. John's Hospital for Skin Diseases, and a living culture was planted in another interdigital space after lightly scarifying. A group of erythemato-squamous papules was produced exactly similar in appearance to the spots which often outlie the intertriginous lesions. I have performed similar experiments on several other cases in which monilia has been discovered in scrapings and subsequently cultivated. In all cases inoculation has produced erythemato-squamous spots, but never vesicles or pustules. The artificial lesions have always cleared up without treatment within two or three weeks. It is, no doubt, impossible to produce the exact conditions which are present in the disease as it occurs naturally, and the short duration of artificial lesions is no argument against the pathogenicity of the organism.

Monilia is an important cause of dysidrosiform eruptions on the hands and feet. These usually occur in association with sodden interdigital erosions, but not invariably. In a case of my own, that of a woman who suffered from a recurrent vesicular eruption on the palms and lateral aspects of the fingers with desquamating areas surrounded by a detached epidermal collar, monilia was found in the scales and cultivated. An artificial inoculation with

her culture produced squamous lesions similar to the desquamated areas.

I have no personal experience of monilia infection of the nails, and I believe it to be rare. I have read the cases, however, described by Pellier in 1914, and by Arit Scott in 1927. Pellier's case was that of a man in whom two of the nails on each foot were opaque, thickened, and friable. Microscopical examination showed very rare mycelial elements and an abundance of large globular and oval spores. The fungus was grown on maltose agar and submitted for an opinion to Professor Vuillemin, who pronounced it as being closely related to *Endomyces albicans*. Arit Scott's case was very similar—that is to say, the nails were opaque, thickened, and friable, resembling, in fact, ringworm infection, but a microscopical examination of the nails and subsequent culture showed it to be monilia.

Cases of mycotic paronychia in which monilia may be found in the pus exuding from the nail fold are now no longer regarded as rare. The essential characters are painful inflammation and bolster-like swelling of the nail folds, exudation of pus from beneath the fold, and in cases of long duration more or less distortion of the nail itself. They occur chiefly in those whose occupations necessitate frequent immersion of the hands in water. The first cases were reported in German literature, and following this several have been described in America and in England.

Shelmire reported a group of cases and experimented on himself with the organisms which he isolated. He inoculated a fresh culture beneath his own nail fold and noted that in twenty-four hours the fold became swollen and tender; acute paronychia developed within four days. The artificially produced condition cleared up within a fortnight. Kingery and Thienes reported a group of cases occurring in the fruit-canning industry; they performed the same experiment on themselves, with the same results. On account of their rapid recovery these authors did not consider their experiments to be positive evidence of the causal relations of the organism to the condition. In view, however, of the similar experience that others have had with regard to the short duration of the lesions produced by artificial implantation of this type of fungus, I believe their pathogenic rôle may be accepted in these cases of paronychia.

I now pass to the more controversial side of this subject—namely, the nature of the spore of Malassez and the part played by it in the common group of dermatoses named by Unna seborrhoeic eczema, by Brocq psoriasiform parakeratoses, by Darier eczemitides, and in England generally known as seborrhoeic dermatitis. I do not propose to attempt a detailed description of the clinical features of this common disease, which, in any case, is well known to us all in its typical manifestations, although I think everyone will agree that cases occur in which the diagnosis may be extremely difficult.

The starting point of seborrhoeic dermatitis is almost always the scalp, which is found to be the site either of the disease itself or of a well-marked degree of dandruff. If a dandruff scale is stained with methylene blue or Giemsa, the fungus known as the spore of Malassez, or pityrosporon of Sabouraud, or flask bacillus of Unna, is readily seen in groups consisting of spores of various shapes and sizes, of which the commonest is the flask-shaped form consisting of a large oval or round body giving off a small roundish process suggesting a budding yeast. Spherical and sausage-shaped forms are also found in sizes ranging to 3.7μ in length by 2.6μ in breadth. Unna believed that the fungus was the cause of pityriasis of the scalp, or dandruff, and that in combination with another organism, which he named the morococcus, it was also the cause of seborrhoeic eczema. His view was that the scales fell from the scalp to the neck, face, chest, and back, and in seborrhoeic subjects gave rise to the disease. This is the view which has been held almost universally up to the present. Unna further expressed the opinion that only by culture of the fungus and artificial reproduction of the disease could its etiology be definitely established. The precise nature of the morococcus is still the subject of various opinions, but, generally speaking, it is regarded as a species of staphylococcus.

For many years attempts have been made to cultivate this fungus, and although fungi resembling yeasts have been grown both from dandruff and from seborrhoeic eczema, few claims have been made that the fungus grown was the actual spore of Malassez. The prior claim to this distinction is that of Mr. W. G. Garner, assistant in the pathological department of St. John's Hospital. He claimed to have cultivated the fungus from dandruff as early as 1908, using maltose agar and acid glycerin agar. Dr. J. M. H. MacLeod and I published, in 1928, an account of the method he used, the morphology and biological reactions of the fungus, and the results of some experimental inoculation in human beings. Templeton cultivated the fungus on beer-wurt agar in 1926. Acton and Panja claimed to have grown the fungus in 1927. Finally, far-reaching claims are made by Benedek with regard to the fungous etiology of the disease. In a recent publication Benedek entirely refutes all claims made in the three publications first mentioned, and states that he alone has succeeded in finding the fungus responsible for the disease and its cultural requirements, and, further, that this organism is not the spore of Malassez, which he regards as a harmless saprophyte, but an ascomycete—in other words, one of the higher fungi.

I will now summarize briefly the observations of each of these writers.

Benedek first grew his organism in 1926; he found its cultural requirements to be 8 per cent. glucose agar, glucose 8, peptone 1, agar 2, distilled water 100. The fungus grew best at a temperature of 27° C. It is grown by inoculating a quantity of material, preferably dandruff, on to the medium. He says that he is able to identify it in the scales of pityriasis of the scalp and seborrhoeic dermatitis in liquor potassae. He describes the organism as a schizo-saccharomyces, because it multiplies by fission rather than by budding. Its elements vary in size between 4.5 and 1.5μ. It is a very pleomorphic organism, and alters a good deal in appearance in old cultures. Short mycelial rods, and elements which he describes as spindle giant cells, often develop after six to eight weeks. He describes asci among the elements, and therefore regards the fungus as an ascomycete. Benedek regards this fungus as the sole cause of pityriasis of the scalp, of seborrhoeic eczema, acne, seborrhoeic rosacea, and, in several cases, of sycosis—admitting, of course, the existence of secondary infection (staphylococcal) in the last-mentioned disease—of certain axillary and pubic abscesses from which he has obtained pure cultures, and of some cases of submammary and axillary intertrigo. He disagrees with Haxthausen and Sabouraud that the pityriasic inflammatory lesions found on the face in children are of streptococcal origin, and considers that the streptococci found are only secondary invaders. He goes, however, much further than this and states that his fungus is the cause of seborrhoea itself. He considers that the words seborrhoea, seborrhoeic eczema, and pityriasis should be given up, and that these conditions should henceforward be called schizo-saccharomycosis. He claims a cure for seborrhoea itself by a vaccine made of his organism. He has been able to cultivate it from the blood, in one case of pityriasis capitis, in seven cases of seborrhoeic eczema, in sycosis twice, and in seborrhoeic rosacea and pityriasis rosea once each.

He believes that the schizo-saccharomyces is never a saprophyte, but is spread from person to person by contagion, especially from barbers' hairbrushes, from which he has invariably succeeded in making cultures, and from parents to children, thus explaining family and hereditary instances of seborrhoea and acne. He regards the scalp as a breeding ground for the parasite, and considers that it acts chiefly through its toxins, the organism responding with two pathological appearances: (1) a very marked eruptive inflammation, (2) fatty degeneration of the tissues. The last is held responsible for seborrhoea.

He produces as proof of the pathogenicity of his organisms the following experimental findings: (1) a positive complement fixation test in all cases of pityriasis or of seborrhoeic eczema; (2) production of papules and in some cases pustules by the killed organism or by its filtrate; (3) cure of cases by vaccine; (4) agglutination tests; (5)

reproduction of the disease by implantation with subsequent recovery of the fungus from the artificially produced lesion.

He describes the result of inoculation as follows: On the sixth day the place is covered with a dry crust; in eleven days scaling is present; nine days later the inoculated part still shows fine scaling. The experiments were made only on those already suffering from seborrhoeic eczema. Benedek thus regards his schizo-saccharomyces as the cause of seborrhoea and of all its complications. His organism, he says, is not the spore of Malassez, and has nothing whatever to do with it. He claims, in fact, to have found the spore of Malassez growing with his organism as a contamination.

Acton and Panja, working in India, claim to have grown the spore of Malassez on Petroff's glycerinated medium, coloured with gentian violet to inhibit the growth of staphylococcus. On this medium the primary cultures appeared as dry chalky white colonies. They gave no account of the morphology or biological reactions of the fungus that they cultivated. Like Benedek, they believe that a fungus is the cause of seborrhoea and of all its complications, but they regard the spore of Malassez as the causal fungus. They also consider that the toxin of the fungus is responsible for hyperactivity of the sebaceous apparatus, which, they point out, is not a true secretion but a speeding up of a degenerative process.

Templeton's method of cultivating the fungus was to comb scales from the scalp with a sterile comb either into a sterile Petri dish or directly on to the medium. Slight but undoubted growth occurred round the scales. Templeton's paper was illustrated by photographs showing round, oval, and some dumb-bell shaped spores obtained from the cultures. He gives no further morphological description.

In 1927 and 1928 MacLeod and I made some observations on the morphological and cultural characteristics, and the pathogenic properties of the organism cultivated by Garner. These observations have already been published, and I will do no more than summarize them as briefly as possible.

The fungus is cultivated from dandruff by scraping scales with a sterile knife on to a sterile watchglass and then planting them on maltose agar, acid glycerin agar, or in oleic acid glucose broth. The formulae are as follows:

Maltose agar:

Agar	1.8
Granulated peptone	1
Chassaing maltose (brut de chanut)	4
Distilled water	100

Acid glycerin agar:

Agar	1.5
Peptone	2
Glycerin	2
Distilled water	100

Oleic acid glucose broth:
Peptone broth *plus* 1 per cent. oleic acid
1 per cent. glucose

On the solid media creamy white or slightly yellow colonies appear in three to four days, frequently contaminated by staphylococci from which they are separated by transplantation to fresh media. The organism is pleomorphic, exhibiting a marked variation in size and shape, with frequent budding forms. Mycelial filaments which are long and narrow and but little septated are found in the fluid medium. The fungus exhibits chemical activity in the presence of various sugars:

In galactose—acidity but no gas formed.
In maltose—acidity with slight gas.
In glucose—acidity with slight gas.
In saccharose, inulin, dulcite, raffinose, lactose, and mannite—no change.

Litmus milk is unaffected. No liquefaction is obtained in gelatin. These reactions differ from those of *Monilia pinoyi*. The elements of *Monilia pinoyi* also are larger on the average in size, and exhibit much less pleomorphism both in shape and size.

This fungus was inoculated after light scarification and by intradermal injection on to the skins of normal subjects, seborrhoeic subjects, and those already suffering from seborrhoeic dermatitis. In normal subjects the results were negative, the fungus when freshly cultivated from dandruff was always pathogenic and produced a group of small follicular papules after twenty-four hours to two or three days. These remained for about a fortnight and then disappeared. In seborrhoeic subjects the same lesions occurred, but in some cases they appeared more active than in normals, the papules being more numerous and irritable. In subjects suffering from seborrhoeic dermatitis the lesions were in some cases absolutely identical with those already present, the inoculated lesion spreading by the formation of fresh papules and clearing in the centre with desquamation. This suggested the existence of hypersensitivity of the individual towards the fungus. In each case the fungus was recultivated from the artificial lesion. In most of the cases the artificial lesions were short-lived, but in some cases they became well established and showed no more tendency to disappear than those already present.

On the strength of this evidence we believed that Garner's organism was in fact the spore of Malassez, and that this fungus alone was probably responsible for seborrhoeic dermatitis. We regarded the pyogenic organisms found constantly in association with the disease as secondary invaders.

More recently I have made comparative tests with monilias cultivated from cases of monilia infection and our fungus, and have observed that sometimes precisely similar lesions may be produced by the implantation of either species. In a case so treated quite recently the lesions not only resembled one another, but could not have been picked out from the rest of the disease, a very typical seborrhoeide. As the two fungi are very near relations, although differing morphologically and in biochemical activity, this result is not at all surprising.

Benedek recently, commenting on our work and that of Templeton, and of Acton and Panja, said that he did not regard any of the organisms described as the cause of seborrhoeic dermatitis, that none of them had anything to do with his organism, and that the value of our observations could be estimated by the fact that three observers had claimed to have cultivated the spore of Malassez, and that each described a different organism. I would like to answer this criticism without making any comparison at the moment of the properties of each respective organism. Acton and Panja gave no description of their fungus; Templeton grew very little fungus, and that which he described appeared to have the same morphology as that described by MacLeod. In any case, it is a well-recognized fact that in mycology the same species, when grown under different conditions, may undergo considerable alterations in morphology. For example, four well-differentiated species of ringworm fungi have recently been produced from one original species by variations in cultural conditions, so that in any case no absolute identity could be expected even if it were agreed that in each case the spore of Malassez had been grown. As Craik says, in an organism as variable as monilia, morphological distinctions are of little value.

The question arises as to what group these fungi belong. There appears to be no doubt that the fungus with which we experimented belongs to the monilia type of yeast-like organism, but that it is a different species from *Monilia pinoyi* and *Monilia albicans*, for example. Benedek describes his organism as a higher fungus, an ascomycete, for the reasons already stated.

I have recently had an opportunity of comparing this organism, through the kindly help of Dr. F. Reiss, professor of dermatology at Shanghai, and the courtesy of Dr. Benedek. Dr. Reiss, who had previously discussed Dr. Benedek's work with him, wrote to him and asked for cultures of his organisms for comparison with ours, a request with which Dr. Benedek kindly complied. Unfortunately, Dr. Reiss was not in England long enough to make any immediate comparison, but he gave me a subculture. This subculture has been examined in the pathological department at St. John's Hospital. I am indebted for the following report to Dr. MacLeod, Dr. Burford, and Mr. Garner.

The organism is unrelated to the spore of Malassez, and consists of:

Rods measuring from 3.5 to 4.5μ by 1.6 to 2.0μ. Occurring singly, spore bearing, motile, Gram-positive. The spores occur both inside and outside the bacillus.

Its cultural characters are as follows: The optimum temperature of growth is 27° C. and the maximum temperature 45° to

59° C. It grows well on ordinary sugar and glucose agar. It does not grow on Sabouraud's maltose agar at any temperature. On agar and glucose agar the growth is a pale yellowish tint. It also grows in broth and on potato. It liquefies gelatin with the production of a greenish tint.

Many sugars are fermented by it.

In raffinose, acid and gas are produced.
In inulin—negative.
In dulcite—negative.
In maltose, acid and gas are produced.
In mannite, acid and gas are produced.
In litmus milk—alkaline, no coagulation.
In salicin—negative.
In glucose, acid and gas are produced.
In saccharose, acid and gas are produced.
In lactose, acid and gas are produced.

Scales from seborrhoeic scalps have been planted out upon 8 per cent. glucose agar and incubated at 27° C., and this organism has been found in association with others.

Implantations after scarification have been made upon the skin, using the spore of Malassez as a control. At the end of fifty-six hours no lesions have appeared in the case of Dr. Benedek's culture, whilst the usual follicular papular lesion has occurred with the implantation of the spore of Malassez.

Dr. Benedek's organism appears to be a sporing bacillus, and unrelated to any yeast forms.

Benedek's claims are clearly too fantastic to gain any wide acceptance. He dispenses entirely with seborrhoea and with Darier's kerosis. In his opinion there is no hereditary element in seborrhoea, only an infection with a pathogenic fungus—that is to say, there is no pre-existent soil on which the fungus will thrive, but a soil that is made by the toxins of his fungus.

Further, from the observations made in the laboratory of St. John's Hospital, it would appear that the organism is not a yeast at all. Even if it were an ascomycete, as he claims, there exists no known pathogenic ascomycete, the only possible near relation to a true yeast being the blastomyces of Gilchrist.

Finally, he states that he regards the spore of Malassez as a harmless saprophyte. In all the fungous infections of the epidermis that I have mentioned at the beginning of this paper the proof of the causal relationship of the fungus in each case is not the fact that it can be cultivated, but that it can be easily seen in the scales produced by the disease. In the stained scale of pityriasis capitis or seborrhoeic dermatitis one can always see the spore of Malassez, but never any other fungus. This fact, I think, is the strongest possible evidence in favour of its etiological significance.

Summary and Conclusions.

From dandruff a fungus can be cultivated which, when implanted on the skin, produces a condition clinically indistinguishable from seborrhoeic dermatitis. It can be recovered from the artificial lesion by culture, and may be seen in a scraping of the lesion. The fungus appears to be a species of the monilia type of fungus, though differing, as demonstrated by MacLeod, from other known pathogenic species of this genus in definite respects. I believe it to be the spore of Malassez for the following reasons:

1. It resembles the spore of Malassez morphologically.

2. The spore of Malassez is always found in dandruff, and is the only fungus that can be seen inside the scales. It may therefore be regarded as the cause of pityriasis capitis, for the same reason that *Microsporon furfur* is accepted as the cause of pityriasis versicolor. Pityriasis capitis or dandruff has been regarded, since Unna, as the starting point of seborrhoeic dermatitis, and the breeding ground of the disease. The spore of Malassez is therefore concerned in the production of seborrhoeic dermatitis.

3. The cultivated fungus is capable of accurately reproducing the disease, not merely a crusted or scaly lesion, but one which is primarily follicular, papular, and ultimately squamous, and which, in many cases, cannot be distinguished from those already present.

4. There are marked individual differences in susceptibility to this fungus. Those with seborrhoeic dermatitis, particularly in the more acute forms, being very sensitive to it, whilst others, especially normal subjects, show a minimal response to it.

I will conclude by saying that if, as I think, the observations of MacLeod and myself which I have just related bring the groups of dermatoses that I have discussed into line with one another, the facts only substantiate the view held by Unna, Sabouraud, and many others, that in essence seborrhoeic eczema is a fungous disease.

DIATHERMY EXTIRPATION OF THE PHARYNGEAL TONSILS.

BY

DAN McKENZIE, M.D., F.R.C.S.Ed.,

SURGEON, CENTRAL LONDON THROAT AND EAR HOSPITAL.

There are many sufferers from chronic septic intoxication, apparently from the tonsils, for whom complete tonsillectomy of the ordinary kind is unsuited. People with cardiac disability, or with exophthalmic goitre, for example, belong to this class, and we must also include patients whose nervous dread of "cutting" renders the operation an ordeal they dare not face. For cases like these surgical diathermy is now being tried, and it bids fair to become the method of choice. Its action can be limited or extended according to desire; the wounds it gives rise to remain aseptic, and there is only a trifling amount of soreness during the separation of the diathermy sloughs. Furthermore, tonsils of all sizes can be extirpated, whether they happen to be small stumps hidden behind the faucial pillar or large hypertrophied tonsils touching each other in the middle line. It is merely a matter of time and patience.

Method.

Tonsils can be diathermized easily and comfortably under local anaesthesia, and, at least until they are reduced to their last remnants, surface anaesthesia is quite sufficient. The surface of the tonsil is painted over once or twice with pure adrenaline solution (1 in 1,000) in order to blanch it, and then with equal quantities of cocaine hydrochloride solution (10 per cent.) and adrenaline solution (1 in 1,000). Towards the end of the treatment, when the bulk of the tonsil has disappeared and we are nearing the capsule, infiltration of the peritonsillar region, and perhaps also of the pillars of the fauces, with 2 per cent. novocain or beta-eucaine solution is advisable in addition to the surface anaesthesia.

For active electrode I usually employ either a short, curved, blunt point, or a short needle, according to the part of the tonsil to be attacked, the indifferent electrode being applied as usual to the arm or back. The blunt active electrode is more useful in the early, and the needle more useful in the later, stages.

At the first séance the blunt electrode is passed into the supratonsillar fossa, the point being inserted as far as the capsule of the tonsil, to which this blind pouch reaches. Then, with a curved vulcanite guard protecting the anterior pillar of the fauces, the current is turned on at zero, and slowly raised in strength until coagulation appears in the tissue around it. The current is then switched off.

Our object in selecting the supratonsillar fossa for the first coagulation is that, as the pathological changes in ordinary peritonsillar abscess show, septic absorption is probably more active here than anywhere else in the tonsil. Further, a large number of crypts open into this cul-de-sac, and these we destroy straight away.

This region, then, having been put out of action, first in the one and then in the other tonsil, the surgeon may or may not proceed further at the first séance. If the patient is nervous and the tonsil small he will probably limit himself on this occasion to a single application of the

diathermy. But if the patient is stout-hearted there is no reason why a little more should not be diathermized.

Subsequent to the operation, as the effect of the anaesthetic wears off, the patient will feel a little soreness, which will continue for a few days. But, particularly if the surgeon is careful to avoid the pillars of the fauces, little or no complaint is made, and the patient is able to submit to the treatment from start to finish without being away from work for a single day.

The first séance is succeeded by others at intervals of about a week or ten days, each time one or two or more areas of about 1 cm. in diameter being coagulated. The length of the course depends, naturally, upon the size of the tonsils and the amount the surgeon feels called upon to coagulate each time. I find the duration of my treatment to be from two to four months. Towards the end of the time there will remain to be disposed of a few isolated mounds or clumps of lymphoid tissue in the recesses of the tonsil bed, and adhering to its capsule and to the faucial pillars. When this stage is reached infiltration anaesthesia may be required, and the needle electrode is then handy for getting at these less accessible remnants.

In general, we avoid too extensive a coagulation at any one séance, chiefly because of the risk of bleeding during separation of a large, deep slough. In view of the possibility of this accident the patient should remain within reasonable reach of the operator throughout, so long as there are any sloughs to come away. Personally, I have not yet seen serious haemorrhage in these cases, but I know that it does occur, and, indeed, circumstances being as they are, an occasional haemorrhage is to be looked for. But there can be no doubt that the risk is minimized if the surgeon contents himself with modest advances and restrains his own and his patient's desire to bring the treatment to an end as early as possible.

By the foregoing method, carried out with care, patience, and perseverance, one can destroy all the tonsil tissue in the pharynx without seriously taxing the patient's fortitude, and with a minimum of scarring.

One interesting observation has been made, and that is, that patients quite frequently report improvement in their remote symptoms—rheumatic pains and so on—immediately after the first applications of the diathermy. The explanation probably is that the diathermy sterilizes the tonsil of bacteria beyond the area coagulated and so cuts off the supply of toxins.

There can be no doubt, in my opinion, that diathermy coagulation will come to be the method of choice for removing tonsils in adults. It is much superior to London paste and the galvano-cautery, and it may even challenge comparison with the ordinary surgical operation, particularly in delicate and nervous adults. It is, of course, unsuitable for children.

ADDISON'S ANAEMIA:

The Occasional Failure of Liver Therapy.

BY

A. H. HOLMES, M.D., B.S.Dunelm.,

late house-physician, Swansea General Hospital.

It has lately become almost a platitude that a case of anaemia which does not respond to treatment by means of a liver diet should not be diagnosed as Addison's anaemia. It is therefore of interest to consider the following three cases, on clinical grounds diagnosed as Addison's anaemia, which failed to respond to liver therapy. With these cases were simultaneously treated others of the same disease which gave a response to liver in every way comparable with that described by Minot and Murphy. Moreover, the methods of diagnosis and treatment employed in both the successful and unsuccessful cases were identical.

Case I.

The patient, a single woman aged 58, was admitted on March 20th, 1928, with a twelve months' history of sensory changes with loss of power in the hands and legs. She had a sister suffering from anaemia, and the only important fact about her previous medical history was that she had been operated on for gall-stones in 1925.

Physical Signs.—The tongue was clean and glazed, but not sore: there was subjective and objective evidence of involvement of the nervous system; achlorhydria was present; the Wassermann reaction was negative. The van den Bergh test gave an indirect positive reaction of 2 units. The blood count was as follows: red blood corpuscles 3,460,000 per c.mm., haemoglobin 77 per cent., colour index 1.26, white blood cells 4,000 per c.mm. Megalocytosis and anisocytosis were present.

Treatment.—On the above evidence a diagnosis was made of subacute combined degeneration of the cord, accompanied by a moderate degree of Addison's anaemia, and treatment with 8 oz. of liver a day and dilute hydrochloric acid was instituted.

Progress.—The treatment was continued for over six weeks, but the blood picture remained unchanged and there was no improvement in the nervous symptoms. The patient was discharged on May 5th, 1928, and stopped taking liver and hydrochloric acid. On December 18th her blood was examined again, and we were astonished to find that the anaemia had spontaneously disappeared and she now had a normal blood count. There was no concurrent amelioration in the nervous symptoms. Further observation on this case was not possible, but an inquiry made in March, 1929, elicited the information that the patient was alive and in much the same condition as when we saw her in 1928.

Commentary.

Clinically this case was one of Addison's anaemia with subacute combined degeneration of the cord, though confirmation of this diagnosis could be obtained only by post-mortem examination. The occurrence of a spontaneous remission afforded proof that the bone marrow was capable of responding to a suitable stimulus, but the conclusion appears inevitable that the liver could not provide such a stimulus in this case.

Case II.

A man, aged 51, by occupation a miner, was admitted on October 5th, 1928, complaining of progressive weakness for twelve months. The patient had one brother suffering from some variety of anaemia, but otherwise his family history and personal medical history afforded no significant data.

Physical Signs.—The patient showed evidence of intense weakness and wasting; he was drowsy and febrile. There was no evidence, subjective or objective, of involvement of the nervous system; achlorhydria was present; the Wassermann reaction was negative; and the van den Bergh test gave an indirect positive reaction of 5 units. The blood count was as follows: red blood corpuscles 1,150,000 per c.mm., haemoglobin 25 per cent., colour index 1.2, white blood cells 2,400 per c.mm. The urine had a specific gravity of 1022, and contained a trace of albumin. Megalocytosis and anisocytosis were present.

Treatment.—The patient was given 8 oz. of liver each day, with liver extract to supplement the deficiency when he was unable to take the full dose. Dilute hydrochloric acid was given as well.

Progress.—The patient went steadily downhill, became comatose, and died on October 24th. On October 15th the blood count had dropped to 1,000,000 red blood corpuscles per c.mm., with haemoglobin 23 per cent. From this date onwards the quantity of liver extract was doubled, and arsenic in the form of sulphostab was administered as supplementary treatment.

Post-mortem Examination.—The liver, kidneys, and spleen gave a marked iron reaction; the haemolymph glands were prominent, and the bone marrow showed the megaloblastic reaction typical of Addison's anaemia. There was no evidence of any complicating disease.

Commentary.

This is a case in which the diagnosis of Addison's anaemia was confirmed by post-mortem examination, and the only reason that can be advanced to account for the apparent failure of liver therapy is that the anaemia was a severe one. It may be suggested that the bone marrow was so overwhelmed with toxins that it had become too far damaged to respond; on the other hand, many patients with low blood counts are known to respond well to liver therapy.

Case III.

This patient, a man aged 45, by occupation a collier, was admitted on October 24th, 1928, complaining of progressive weakness for ten months, loss of weight and sore tongue, and gastro-intestinal disturbances.

Physical Signs.—The patient was weak and showed signs of wasting; his tongue was clean and glazed, his spleen palpable, and evidence was obtained, both subjective and objective, of involvement of the nervous system. The Wassermann reaction was negative; the van den Bergh test gave a positive indirect reaction of 5 units. The blood count was as follows: red blood

corpuscles 1,100,000 per c.mm., haemoglobin 23 per cent., colour index 1.1, white blood cells 2,400 per c.mm. Megaloblasts and megalocytes were present, and there was also anisocytosis.

Treatment.—This was the same as that given in Case ii.

Progress.—The patient continued to become weaker, and on December 5th, despite a blood transfusion performed early the same day, he died.

Post-mortem Examination.—The liver, kidneys, and spleen gave a marked iron reaction, and the bone marrow showed a megaloblastic reaction. No other disease was present, except anthracosis of the lungs.

The remarks applied to Case ii by way of comment also apply to this last case.

These three cases afford some evidence against the prevalent view that every true case of Addison's anaemia must necessarily be benefited by liver therapy. So far, very few unfavourable results following this treatment have been published, but two of Fraser's series failed to respond for no accountable reason. G. Guiani of Genoa found that 15 per cent. of his cases gave no response to liver, but possibly many of the patients were moribund when they came under treatment, and their bone marrow was thus unable to respond. If the existence of a small proportion of unsuccessful reactions to liver therapy is established it must materially alter the prognosis of Addison's anaemia; above all, it imposes the necessity of withholding the promise of a hopeful outlook until the effect of liver administration has been observed for a sufficient period.

It has not been suggested that liver destroys the exciting cause of the anaemia. As, moreover, it is known that agents as essentially different as malaria and benzol can give rise to an Addisonian anaemia, it is probable that there are many different exciting causes, and it can hardly be expected that liver should prevail against every one of them. It seems reasonable, then, to assume that in some cases the exciting cause is so powerful that it overcomes any benefit that might be expected to accrue from the administration of liver.

In conclusion I wish to thank Dr. A. F. S. Sladden, pathologist to the Swansea General Hospital, who examined the blood in each case and conducted the post-mortem examinations, and Dr. Daniel E. Evans, senior physician to the Swansea General Hospital, who allowed me to investigate and report on the cases.

THE ACETIC ANHYDRIDE TEST IN CEREBRO-SPINAL FLUID.

BY

FREDA K. HERBERT, M.A., M.B., B.S.,

ASSISTANT PATHOLOGIST, BELGRAVE HOSPITAL FOR CHILDREN.

(From the Department of Chemical Pathology, St. Bartholomew's Hospital.)

This test was described in 1923 by Boltz, who found positive results in all cases of general paralysis and certain other types of neuro-syphilis. During the next few years various authors concluded that the reaction was of diagnostic value in these conditions. The test is performed as follows: to 1 c.cm. of the cerebro-spinal fluid 0.3 c.cm. of acetic anhydride is added, and the mixture is shaken; 0.8 c.cm. of sulphuric acid is added very gradually, drop by drop. A positive result consists in the development of a colour which has been described as "blue-pink," "lilac," or "purple."

The test is similar to the glyoxylic reaction of Hopkins and Cole, which was discovered as a result of their investigation of a test for protein described by Adamkiewicz. This consisted in the development of a violet colour when protein was treated with glacial acetic acid and concentrated sulphuric acid. Hopkins and Cole showed that the reaction was dependent on the presence of glyoxylic acid as an impurity in the acetic acid. The constituent of proteins responsible for the reaction with glyoxylic acid is *tryptophane*.

In 1927 the similarity between the "Boltz test" and the glyoxylic reaction was pointed out by Duncan, by Blix and Backlin, and by Walker and Sleeper. These authors brought forward evidence that the acetic anhydride test was identical with the glyoxylic reaction, and that the positive results in cerebro-spinal fluid were due to protein. Positive results were obtained when the acetic anhydride test was applied to tryptophane solutions, or to egg-albumen solutions of concentrations of 0.03 per cent. and over. As would be expected from these facts, it was found that many non-syphilitic cerebro-spinal fluids yielded positive results.

The appearance recently in the *British Medical Journal* of a paper by Piotrowski prompts me to draw attention to these findings, and to record some personal observations which confirm the view that the acetic anhydride test is *a protein reaction similar to the glyoxylic reaction.*

Several samples of acetic anhydride were examined, and all gave a positive reaction with protein. The less pure samples gave the more intense reactions, but the purest samples obtainable gave positive results. The colour produced showed the same absorption spectrum as the colour produced in the glyoxylic reaction.

A series of twenty-four cerebro-spinal fluids from various cases was tested; these included cases of epilepsy, cerebral tumours, general paralysis, disseminated sclerosis, hysteria, and various types of meningitis.* The intensity of the colour given in the "Boltz test" was roughly proportional to the total protein content of the fluid, and the colour given by fluids from cases of general paralysis was indistinguishable from that given by fluids of the same protein content derived from non-syphilitic patients. For example, the fluid from a case of general paralysis (total protein 0.18 per cent.) and the fluid from a case of meningitis (total protein 0.15 per cent.) gave colours exactly similar in tint and intensity. On another occasion the fluid from the same case of general paralysis had a lower protein content (0.05 per cent.), and then gave a negative result with the "Boltz test."

It appears impossible to fix a limiting concentration of protein below which the reaction is negative. Apart from the variations in the samples of acetic anhydride used, there are variations in the conditions of the test as ordinarily employed. The heat developed during the addition of the sulphuric acid is an important factor, and different results can be obtained with the same protein solution by varying the rate at which the sulphuric acid is added. If the mixture is carefully cooled after the addition of each drop of sulphuric acid, so that the temperature of the mixture is not allowed to rise above room temperature, no colour develops, even in fluids which give a definitely positive reaction when treated in the ordinary way. This applies to the fluids from cases of general paralysis as well as non-syphilitic cases. If the mixture, which has been kept cool during the addition of sulphuric acid, is subsequently heated the typical colour develops.

Owing to the crude method by which the test is usually performed, a definite limit of protein concentration below which reactions are negative cannot be fixed accurately, but, in my experience, with pure samples of acetic anhydride it is approximately 0.03 to 0.05 per cent.

It is therefore probable that the "Boltz test" is a protein reaction similar to, or identical with, the glyoxylic reaction. It may be due to some substance (? glyoxylic acid) present as an impurity in the acetic anhydride, or derived from the acetic anhydride in the course of the test. If acetic anhydride is completely hydrolysed by heating with an excess of water for an hour under a reflux condenser, the product still gives the violet colour with protein on addition of sulphuric acid.

If the view here taken is correct, it seems surprising that the test should ever have been regarded as diagnostic of syphilis of the central nervous system. As far as the earlier papers on the subject are concerned, the explanation seems to be the lack of fluids of high protein content among the non-syphilitic controls. In the investigations of Boltz, Grossman, and Harris all the fluids came from patients with mental disease. No figures for the protein content of the fluids are given, but in any such series it would be expected that the syphilitic fluids would have the highest protein content.

Among those who regard the test as diagnostic of general paralysis or neuro-syphilis, Greenfield and Carmichael seem to be the only authors who have studied non-syphilitic cases

*For the majority of these fluids I am indebted to Dr. E. A. Carmichael.

in which the total protein content of the fluid was raised. These authors make a distinction, which in my judgement is not possible, between the "clear lilac" colour of a positive test, and various other tints—for example, "brown-lilac," "pink-blue," "lilac-pink," or "brown"—which they consider negative. I think that most of these colour reactions should really be regarded as positive, and that some of the "brown" colours may be the result of charring of organic matter by the sulphuric acid. The question of the identity or difference of tints can be decided by any worker by the simple method of comparing a patetic fluid with a protein solution of the same concentration.

There remains to be considered the recent paper of Piotrowski, who has found positive results with the "Boltz test" in cases of general paralysis, cerebral and meningeal syphilis, meningitis, cerebral degeneration, poliomyelitis, and in a few normal fluids. When one bears in mind the irregularities in the conditions of the test it seems that these results give no evidence against the view that the protein of the fluid is the reacting substance. Piotrowski mentions a negative result in a fluid with 0.025 to 0.035 per cent. protein, and positive results in seven cases of cerebral degeneration in which the "albumin" was "normal." In four out of ten of his cases of general paralysis the "Boltz test" was negative, but in these the "albumin" was below 0.035 per cent. Two cases of tuberculous meningitis with an "albumin" content of 0.044 and 0.025 gave a negative Boltz test, others gave positive results.

Summary.

The "Boltz test" is regarded as a protein reaction similar to, or identical with, the glyoxylic reaction; no information of diagnostic value is to be obtained from it, apart from its being a rough guide to the protein content of the fluid, which is better estimated by the usual methods.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A FULL-TIME EXTRAUTERINE PREGNANCY.

THE following case seems worthy of record on account of the difficulty of arriving at a correct diagnosis.

On May 20th, 1929, a married woman, aged 44, consulted me because of increasing swelling of the abdomen and general physical ill health. She had had eight children, of whom the last was born seven years ago. The labours had been normal. The periods were regular up to June 8th, 1928, and then ceased; so that to date she had had eleven and a half months' amenorrhœa. She thought she was pregnant, and engaged a midwife for March. She had a severe attack of pain in November, and another in January, which confined her to bed for a week each time. Since January she had not been conscious of foetal movements; she had not consulted a doctor.

The patient was heavy-eyed, sallow, toxic-looking, and rather emaciated. The abdomen had a tense, somewhat tender swelling reaching to the xiphisternum; its size was that of a large normal pregnancy. No foetal sounds were heard or parts palpitated; a non-pregnant cervix of the uterus was felt by vaginal examination. A diagnosis was made of ovarian cyst with some adhesions. Operation was advised and the patient admitted to hospital.

Operation.—The operation was performed on May 24th under general anæsthesia. A subumbilical incision was made and subsequently enlarged. When the peritoneum was opened a cyst wall appeared with so many adhesions to the abdominal wall that malignancy was diagnosed, and preparations made to abandon the operation. Before doing so it was deemed wise to tap the cyst. Grumous fluid came away through the trocar and, finally, a finger was put in to feel for malignant nodules, and so confirm the diagnosis. To our surprise a foetal part was felt. The incision was then further enlarged, and a full-time macerated foetus was delivered. An attempt was made to remove the placenta, but this was found difficult to detach. Owing to the extreme thinness of what were supposed to be the uterine walls it was considered wisest to remove the uterus. It was found to be adherent to the abdominal wall, transverse and ascending colon, omentum, and bladder, and a careful dissection was required to free it. To enable the cyst to be removed a portion of its wall had to be left attached to the transverse colon, and was subsequently removed by another dissection. The bowel had to be sutured, as submucous membrane had been exposed. Finally, on exploring the pelvis, it was seen that there was a small, non-pregnant uterus. The right broad ligament was clamped, and, leaving the right ovary behind, the uterus was removed supravaginally with the attached cyst. It was then observed that there was no left ovary or Fallopian tube, this being involved in the large cyst and attached as a broad band to the left upper part of the uterus. The specimen, when removed, was seen to consist of a small, non-pregnant uterus and, attached to it, a cyst, which was apparently formed from the left ovary and tube, and contained amnion and chorion, with portions of placenta.

Dr. E. Wordley (pathologist to the South Devon and East Cornwall Hospital) reported that the cyst wall consisted simply of fibrous tissue, there being no evidence that it was either muscular or ovarian.

The patient made a good recovery after the operation, and was discharged to a convalescent home at the end of three weeks. The injured bowel gave no trouble.

My thanks are due to Dr. Millicent Fox for administering the anæsthetic.

Gynæcologist, The Greenbank Infirmary, Plymouth.

TRAUMATIC BILATERAL PNEUMOTHORAX: A SIMPLE METHOD OF TREATMENT.

IN view of the recent reports on cases of pneumothorax in the *Journal*, the following case appears worthy of note.

W. D., aged 23, single, was run over by a journey of full trams, while engaged at his work underground on June 17th, 1923. The accident occurred at about 11 a.m., and he was conveyed to the Aberdare and District General Hospital, where I saw him at 12.30 p.m. He was then in a condition of shock. His pulse was weak, rate 120, respirations rapid and shallow, colour bluish. He complained of pain all over the body, but principally in the region of the sternum and on either side of his spine.

Examination showed fractures of both clavicles and several ribs on both sides. There was subcutaneous surgical emphysema in both axillæ and at the site of the fractured clavicles. The usual treatment of shock was instituted and a many-tailed bandage applied around the chest.

He was seen again one and a half hours later. His condition was truly remarkable. He was quite blue, respiration was practically absent, the pulse was imperceptible, and he was cold all over. Percussion note was tympanitic all over the chest. His neck, as such, had ceased to exist; on either side from the zygomatic arch to the lower border of the pectoralis major the subcutaneous tissues were enormously distended with air. The skin presented a uniformly convex surface, and he looked like some weird fish, all head and shoulders. The emphysema also extended over the ribs on either side towards the back.

It was evident that something would have to be done quickly as the man was dying from asphyxia. The emphysema was displaced by pressure from the lower part of the right axilla, the ribs defined, a puncture made through the skin with a scalpel, and an ordinary hydrocele trocar and cannula pushed through the intercostal space. On withdrawing the trocar air could be heard hissing out. His condition immediately improved. Respiration, pulse, and colour became better. After the first escape of air, during inspiration air could be heard entering the pleural cavity and leaving it during expiration. A simple method of further emptying the pleural cavity was adopted. During inspiration a finger was placed over the cannula and removed during expiration. In this way the lung was enabled to expand further, for at each expiratory effort air escaped from the cannula. After some twenty breaths the cannula was removed. The patient's condition was now greatly improved. In half an hour the procedure was repeated on the left side of the chest.

The following day his condition was good; both lungs appeared to be fully expanded, and the superficial emphysema had considerably subsided. He made an uninterrupted recovery, and has been working underground ever since.

Subsequent *x*-ray examination revealed, besides the fracture of the clavicles, fractures of the fifth, sixth, seventh, and eighth ribs on the right side, and of the seventh, eighth, and ninth on the left, all being broken posteriorly near the angles.

This patient was shown at a clinical meeting of the South Wales and Monmouthshire Branch held at Aberdare in 1927.

The case is interesting for three reasons. First, the rarity of a bilateral traumatic pneumothorax with complete recovery. Secondly, the simple and dramatic way in which the condition was relieved. Thirdly, as to the nature of the internal injuries. I think that both lungs and pleura on each side must have been torn, and yet the patient hardly ever coughed during his illness and had no haemoptysis or melæna.

HARRY BANKS, M.B., F.R.C.S.Ed.,
Honorary Surgeon and Radiographer, Aberdare and District General Hospital.

TRAUMATIC PAROTID HERNIA IN A CHILD.

AMONG the peculiar accidents to which children are prone while playing I think the following is sufficiently rare to be recorded.

A mother brought a girl, aged 5, to the Louth Hospital on August 31st. She stated that the child had been playing with a dog leash attached to a stable wall, and had placed the spring hook in her mouth. Frightened by a peal of thunder, she ran towards the house, but was pulled backwards by the leash. The mother went at once to her assistance and found that the leash was embedded in the cheek in such a manner that one hook gripped the cheek on the outside while the other was gripping the cheek on the inside of the mouth. She freed the child from the leash, and seeing that she was unable to close her mouth, brought her at once to hospital.

On examination the child presented the "dislocated jaw" appearance, the mouth being held open, and saliva running from each angle. In the mouth a globular swelling about the size of a walnut was seen to protrude from the mucous membrane of the cheek high up on the right side opposite the second molar tooth. This I found to be a hernia of the parotid gland. The mechanism of the injury was as follows. The hook on the inside of the mouth had torn through the mucous membrane, piercing the buccinator and masseter muscles, and tearing through the parotid duct; the hook on the outside of the cheek had caused that portion of the parotid which overlies the masseter to herniate into the mouth. I enlarged the wound sufficiently to allow the major portion of the gland to be replaced; but finding that the duct was torn off almost into the gland, I stitched the portion of the parotid from which the duct emerged to the torn edges of the mucous membrane.

The wound healed in a few days, and the resultant parotid fistula into the mouth is a good physiological result, and does not inconvenience the child in any way.

RALPH MORTON, F.R.C.S.Ed.,
Honorary Surgeon, Louth and District Hospital.

A PIECE OF STICK, FIVE AND A HALF INCHES LONG, IN THE SMALL INTESTINE.

THE following interesting case is, I think, worthy of publication.

A Hindu woman, aged 21, was admitted to Kalna Mission Hospital on April 17th, 1929, complaining of pain over the appendix region, which became considerably worse when she was sitting down or squatting.

History.—After the patient had been pregnant for about three months a native *midwife attempted* to procure abortion by the use of sticks. Three were inserted. The woman aborted completely two or three days later, but only two sticks were returned. Ten days later abdominal pain started, mainly on the right side, and she had difficulty in standing up straight; there was no fever. Two months after that she came into hospital.

On admission the patient was unable to stand straight, and could only walk with difficulty. She complained of pain in the right iliac region. A distinct swelling was observed over the position of the appendix; the swelling was hard and brawny, and about the size of a large orange. Vaginal examination revealed a retroverted uterus, and the swelling referred to could be felt from the anterior fornix. A blood count revealed the presence of a leucocytosis of 10,000 per cubic millimetre.

Operation.—The following day the patient was operated on. A right rectus incision was made. As the knife went through the swelling there was a grating sound like that made when cutting a scirrhous carcinoma; the incised tissue proved to be the wall of an abscess situated in the rectus muscle. About a teaspoonful of pus oozed up; this was mopped away and the incision deepened. No more pus was found, and, as the abscess did not seem to account for all of the trouble, the peritoneum was carefully opened. Some adhesions to the abdominal wall were separated off, and then a piece of small intestine was seen to be pointing up like the top of a bell tent; it seemed as if there was a piece of stick inside. The intestine was accordingly opened with all precautions, and a piece of stick (afterwards found to be 5½ inches long and 1/4 inch thick) was drawn out; there was a little escape of faeces. The hole in the intestine was closed with silk and the peritoneum and muscular layers with catgut. Two *drains* were inserted, and the patient put to bed in the Fowler position. Apart from a superficial breakdown of one inch of the wound the patient made an uninterrupted recovery, and was discharged cured three weeks and five days later.

We do not pretend to know exactly how the stick got into the small intestine. Our idea is that it passed originally through the anterior fornix of the vagina into the abdominal cavity, and that it thereafter piereced the abdominal wall internally, causing the abscess mentioned. After that the stick presumably worked its way gradually into the intestine, peritonitis being prevented by the adhesions which formed. We are not sure of the nature of the wood. One of us (J. K. M.) thinks it may be oleander.

Reports of Societies.

ERGOT AND THE PHARMACOPOEIA.

AT the meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on November 12th, with Dr. PHILIP HAMILL in the chair, a paper on the best method of including ergot in the *British Pharmacopoeia* was read by Dr. J. H. BURN and Mr. F. WOKES.

The authors described an investigation which had been carried out by the Pharmaceutical Society of Great Britain, with a view to determine the proper way in which ergot might be included in the *British Pharmacopoeia*. It was now generally admitted that the action of ergot on the patient was due to the specific alkaloid. Histamine had an action on the human uterus, but this was only exerted appreciably when histamine was injected in a dose too large to be suitable for general use. The questions which arose were, how best the drug could be extracted, and how long the preparations kept in a condition in which their potency was maintained; a further question was as to how much alkaloid one ought to expect to get in different samples. A standard had been set in the United States as a result of mixing ten samples of ergot and keeping the extract for six months. The British Pharmaceutical standard at present was 0.05 per cent. ergotoxine, and any product which did not reach that strength was not given a certificate. It had been found that ergotoxine was not easy to remove from the drug. The ergots received from Eastern Europe—Poland and Russia—were of poor quality, while those from Spain and Portugal were rich; no Polish or Russian ergots should therefore be used by the manufacturers. Liquid extracts of ergot deteriorated rapidly on standing, and therefore required to be specially made every two or three months. The samples tested showed a more rapid deterioration at the higher temperatures than at the lower. The ergotoxine itself also lost strength quickly. When it was kept in an ice-chest the loss of activity was not so marked, and reduction to half strength took three times as long. The solid extract was rather more stable, and the time required for it to be reduced to half strength was from sixteen to forty weeks, as compared with eight to twelve weeks in the case of liquid extracts. Experiments on the storage of ergot were still proceeding: so far it had been found that the powdered form took over two years for a 50 per cent. deterioration to occur. If the drug were de-fatted also it became more stable. Therefore, if liquid extract was to be used at a fairly constant strength it would have to be freshly prepared at least every three months, and the most practical solution appeared to point to the use of ergot in the powdered, de-fatted condition. The authors then described some experiments which had been carried out on cats, in which it had been found that the effect of the administration of ergot in stimulating portions of the uterine muscle was not transient, but remained in the system for a considerable time. The possible danger in the human being of a cumulative effect ought not to be overlooked. Of this danger the occurrence of headache could be taken as a definite warning.

Dr. HAMILL spoke of the amount of work and the time involved in carrying out this research, and added that it was disquieting to reflect that people had for years been administering ergot in faith, although, as shown by Dr. Burn, it had not contained appreciable quantities of ergotoxine. He asked whether members had had the opportunity of comparing clinically the effects of guaranteed ergots with the effects of those usually obtained. One patient who had suffered from slight recurrent menorrhagia had had it controlled conveniently by a dose of ergot six hours beforehand, and for twelve months she had had this from the same bottle, kept at room temperature, and he was not aware that she had had to increase the dose in consequence. Dr. IZOD BENNETT said that gynaecologists used solid ergot in association with quinine, and certainly secured a reduction of uterine pains and other symptoms.

THE PASSING OF SUPERSTITION.

AT a meeting of the Section of Psychiatry of the Royal Society of Medicine, held in the Wellcome Historical Medical Museum on November 12th, Sir ROBERT ARMSTRONG-JONES gave a lecture on superstition.

Superstition, he said, was the encroachment of faith on the rights of reason. It was most often founded on ignorance, and it was difficult, therefore, to explain its existence among educated people. Psychologically, superstition was suggestion based upon the instinct of fear, although curiosity—the yearning to know the future—and the instincts of reverence and awe both had a part in it. The term did not cover innocent mistake, but a wilful belief contrary both to experience and to common sense. Much superstition among less civilized people was misinterpretation of beliefs held by those who were more cultured and educated; included were beliefs in giants, dwarfs, fairies—which were the personification of Providence—fays and elves, hobgoblins and gnomes, spirits and genii, which helped to explain the actions of daily life. Emblems of the seasons, the sun, moon, and planets, were personified to account for human actions which they controlled. The belief in demons prevailed among the people, although it was opposed by the clergy; but in the sixteenth and seventeenth centuries it was heresy not to believe in witchcraft, though this belief led to extreme cruelty and to wholesale destruction of human life. Omens were sought everywhere—in the flight of birds, in the power of numbers, in the heavenly bodies, and in rivers. Many who confessed that they were under the influence of witchcraft were undoubtedly insane and victims of cerebral disorder, but they were generally regarded to be possessed by demons. Some of the possessed suffered from *folie à deux* or communicated insanity, which spread like an epidemic of mental influenza all through Europe. They were treated with great cruelty; they were chastised and tied with chains to holy crosses, and whipped. Some were immersed in holy wells, others dosed with medicinal herbs from the monastery gardens and with powerful cathartics and emetics. Polypharmacy prevailed, and patients had to chant psalms and prayers while they partook of loathsome mixtures. When cure did not take place the blame was put on the patient for his failure to observe the impossible conditions that were imposed upon him while he took the remedy. In healing, the help of precious stones was also elicited; there were healing stones, some with holes for the patients to pass through and some to be worn as talismans or carried on the person as amulets or charms. The royal touch also had healing virtues; Samuel Johnson was touched for scrofula by Queen Anne, and Charles II touched over 100,000 sick persons. Probably the expectation and pleasurable hope of cure helped to raise the bodily resistance to disease by increasing the activity of the vital functions. Ancient customs and maxims, said Sir Robert Armstrong-Jones in conclusion, had to-day lost their cogency, and Pavlov's experiments had shown that an idea could cause changes in the blood, just as changes in the endocrine secretions could vary ideas. Old traditions were now despised, and superstition had ceased to be accepted in explanation of the actions of our daily lives. With the passing of superstition, he asserted, the treatment of insanity had been revolutionized.

CAUSES OF INTESTINAL OBSTRUCTION.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, on November 1st, with the president, Mr. R. ATKINSON STONEY, in the chair, Mr. S. B. CLERY read notes on two cases of intestinal obstruction, and demonstrated specimens.

Mr. Clery said that in his first case intestinal obstruction was caused by swallowing a ring, while in the second an intussusception was found.

A man, aged 65, stated that eighteen months ago he had passed some bright red blood per rectum, and he had suffered from diarrhoea for one year. He took purgatives, but did not consider himself constipated, and he had not noticed any mucus in the stools. Two days before admission he had an attack of abdominal pain, and vomited. Castor oil and an enema produced a good evacuation. But next day he vomited again. On the morning of admission to hospital an enema was given without result.

Visible peristalsis of the ladder pattern was noted in the abdomen, and a smooth, firm mass was found in the right lower quadrant, extending upwards to above the anterior superior iliac spine; it was tender, and dull on percussion. At the operation, the mass, which proved to be distended ileum, was found to extend to the floor of the pelvis and to within two inches of the ileo-cæcal valve. The patient's condition becoming suddenly critical, it was considered that he would not survive resection, so enterostomy was performed. Next day the patient looked well, and a quantity of bran-like material and a plum stone came through the enterostomy. On the fifth day after operation he became worse, and two days later he died. At the post-mortem examination the distended ileum was found to be gangrenous in places, and a small brass ring was discovered at its distal end, impacted, and partly buried in the gut wall. This had produced partial obstruction. Orange pips, fruit stones, and the debris of undigested brown bread formed the large palpable mass, and had obstructed the lumen already stenosed by the ring.

The second patient, a married woman, aged 52, had complained of severe abdominal pain and vomiting. She stated that for the previous three weeks she had suffered from attacks of burning pain in the lower abdomen, occurring about half an hour after meals. Three days before admission the pain became violent and continuous, and she vomited several times. The patient looked collapsed, and the abdomen was rigid and tender all over, the point of maximum tenderness being two inches below and an inch to the right of the umbilicus. An ill-defined mass could be felt in this region, extending to the right iliac fossa. At the operation an intussusception of the ileum about nine inches long was delivered into the wound. As it resisted attempts at reduction it was resected, the continuity of the bowel being re-established by anastomosis. When the clamps were removed from the resected portion of intestine, a worm (ascaris lumbricoides) emerged from the proximal end. On the second day after the operation the patient vomited, the vomited material containing a round worm. Ten days later a second worm was passed in the faeces, and two days afterwards another was passed. The patient left hospital after six weeks, with the wound healed.

Mr. J. L. KEEGAN asked whether Mr. Clery regarded the presence of worms as a contributory cause of the intussusception. He thought that it was not unusual for post-operative adhesions to produce such a condition in adults, and mentioned a case which he had seen after gastro-enterostomy, in which he had found a reducible intussusception of the lower intestine. Mr. SETON PRINGLE mentioned a case of intussusception due to Meckel's diverticulum in a girl of 17, in which he had removed the diverticulum and the apparent fat on top of it, which on section proved to be pancreatic tissue.

Mr. CLERY, replying, said he had been unable to find any authority for associating round worms with an intussusception. In this case he could not discover any cause for the condition, but the long-standing history made him think it was a case of chronic intussusception on which obstruction had been imposed. He had seen two other cases of intussusception in adults, in both of which the mass protruded at the anus.

Diaphysectomy for Osteomyelitis.

Mr. SETON PRINGLE showed a specimen taken in the fourth week of a case of osteomyelitis in which there was complete separation of the lower epiphysis of the femur. Mr. Pringle thought the only possible procedure was to excise the lower end of the diaphysis. He had never before performed diaphysectomy of the femur in the acute stage, though he had often done so in the chronic stage. He had no doubt that the lower end of the femur would regenerate satisfactorily.

The PRESIDENT said it was rare to see these cases in the acute stage. They usually appeared in the chronic stage, and it was very difficult to cure them. He always feared that in removing the lower end of the diaphysis he might run the risk of taking away bone-forming material. Mr. W. PEARSON reported a very similar case. When seen, the patient was in a favourable state, and the result of operation was successful. He would regard Mr. Pringle's case as being in the sub-acute stage, rather than the acute, and thought diaphysectomy a mistake in the acute stage. He had lately seen a patient on whom he had operated some years ago; she had perfect function in the knee, but nearly two inches shortening.

Sir W. I. DE C. WHEELER agreed that the case was in the subacute stage. It was hard to explain how after four weeks the inflammation and bony changes would be limited to the lower third of the femur. Most of the cases of

diaphysectomy of the femur which he had undertaken were of a subacute nature, comparable with those in the series published by Stiles. There was a pronounced osteoblastic periostitis with a sequestrum occasionally. Stiles had described these cases as tuberculous, but in many respects they resembled cases of pyogenic origin. The speaker's opinion was that there were two infections. With regard to the possibility of failure in the formation of new bone, in his experience bone was rapidly formed in the case of children, and it was difficult to detect in a skiagram taken years afterwards where the bone had been removed. He showed several photographs to illustrate the rapid formation of bone when the diaphysis was excised in children with old-standing unreduced fractures about the elbow.

Mr. R. Macauley said that in Mr. Pringle's case diaphysectomy was the ideal treatment, but, in his own opinion, it was not the treatment to be advised in the ordinary case. After diaphysectomy of the lower end of the femur, considerable shortening was usual, though secondary trouble did not occur. He mentioned a new method of draining, but thought equally good results should be obtained by the ordinary procedure. Mr. A. B. Clery was surprised that Mr. Pringle had not cut through the bone into the medulla; the speaker had invariably found pus when he did so.

Cyst of the Common Bile Duct.

The President read a paper on cyst of the common bile duct, and reported a case occurring in a woman aged 23.

There was a sudden and rapid development of a cyst in the right upper quadrant of the abdomen, accompanied by pain and increasing vomiting; no jaundice was noticed at any time, and the stools were normal in colour. The condition was complicated by bronchitis, and thrombosis of both femoral veins, more severe on the left side. A probable diagnosis was made of the presence of a retroperitoneal dermoid undergoing malignant degeneration; owing to rapid wasting of the patient from the incessant vomiting, an operation was performed under rectal ether anaesthesia. A cyst was revealed which was pushing the stomach and duodenum to the left. On exploration with a trocar, it was found to contain bile; four pints were withdrawn which were at first clear, but, later, were mixed with muco-purulent material. The gall-bladder was pushed to the right, and was collapsed, with thickened walls. A tube was passed into the cyst and the abdomen was closed.

The patient improved rapidly, but all the bile escaped through the tube at the rate of between twenty and thirty ounces daily, and the stools were clay-coloured. Six ounces of bile with four ounces of saline were injected daily per rectum. At the end of seven weeks, as there was no diminution in the escape of bile and no coloration of the stools, a second operation was undertaken and the cyst was anastomosed to the duodenum. On the following day there was no escape of bile from the tube, but subsequently the discharge of bile returned. On the fourth day there was a leakage of bile from the operation wound, and on the following day of gas and duodenal contents. The patient rapidly went downhill; on the seventh day there was a sudden rise of temperature to 103°, and on the next day death occurred.

The President remarked that only about sixty-eight cases of this condition of idiopathic cyst of the common bile duct had been recorded, with twenty-two recoveries and thirty-nine deaths.

Sir William Whitla said that in 1910 he saw a patient who had been operated on a year previously for what appeared to be obstructive jaundice. The jaundice persisted, and when the patient consulted him he had all the symptoms of stone in the common duct. After careful exploration of the biliary tract nothing could at first be found to account for the symptoms, nor for the dilatation of the common duct which was present. Finally the duodenum was opened, and a tense cyst presented, which apparently involved the intramural portion of the duct. On opening the cyst the operation field was flooded with bile. The duodenum was closed and the patient made an uneventful recovery. The speaker had a case at present with a pure culture of *B. coli* in the bile, but he thought this form of infection was rare.

Mr. F. J. Morrin mentioned a case of jaundice admitted to hospital in which there was a large tumour palpable on the right side. An operation revealed a large swelling, and aspiration disclosed pure bile. At the time of operation Mr. Morrin did not realize that he was dealing with a case of cyst of the common bile duct, and only came to this conclusion later.

The President, replying, said he did not think Sir William Wheeler's case could be described as an idiopathic cyst of the common bile duct. It seemed to him more like the condition found in malignant disease of the head of the pancreas, where there was enlargement, but not a true cystic condition. *B. coli* in pure culture was uncommon in these cases, but a pure culture was obtained from the bile in one case, which was associated with recurrent jaundice and intermittent fever. The only instance of anastomosis between the gall-bladder and stomach being employed for this condition was in a case reported by Taylor. The general opinion seemed to be that it should be possible to effect an anastomosis between the cyst and the duodenum.

RADIOLOGY AND MEDICINE.

At a meeting of the Brighton and Sussex Medico-Chirurgical Society on November 7th, Dr. W. Barrington Prowse delivered his presidential address, which was entitled "Something of *x* rays, and their place in medicine."

Dr. Prowse began with an account of the discovery of *x* rays, with particular reference to the work of Sir William Crookes. He described the production of *x* rays in a Crookes tube, and commented on the revolutionary change in thought which radio-activity and radium had imposed upon the science of chemistry, and the conception of scientists of the nature of matter and the construction of the atom. Dr. Prowse then gave a short historical account of the application of *x* rays in medicine and surgery, and enumerated the more important improvements in apparatus and technique. He discussed the problems of interpretation, and condemned the haphazard production of *x*-ray pictures, and their too frequent use for unsuitable purposes. The speaker pointed out that *x*-radiation, though not essential to life, had, in common with radiations of other wave-lengths, the power of influencing life and health; its influence might be stimulating and beneficial or depressing and destructive, according to whether the rays were administered in moderate quantity or in excess. Scepticism with regard to the efficacy of *x* rays in disease was partly due to the number of widely differing complaints for which they had been recommended. After describing the action of *x* rays in health and in disease, mention was made of the varying susceptibilities of different healthy and diseased tissues to the rays. *X* rays might be used, according to the effect desired and the condition under treatment, either in stimulating and alterative doses or in destructive ones. Examples were given of some conditions in which they were particularly useful, and special reference was made to their use in malignant disease. Dr. Prowse advocated a more extensive use of pre-operative raying, and also spoke strongly in favour of employing radiotherapy instead of surgery in periosteal sarcoma. Where both radiotherapy and surgery eventually failed was in the control of metastasis. After briefly indicating the use of *x* rays in exophthalmic goitre, uterine fibromata, and some other conditions, including diseases of the skin, Dr. Prowse concluded with an appeal to medical practitioners to co-operate more closely with radiologists in the diagnosis and treatment of disease.

Two cases were cited—one of carcinoma mammae and one of sarcoma. Both patients had received no other treatment than *x* rays, and in each instance the patient was alive and well at present without any sign of recurrence, five and a half years after irradiation.

THE DENTAL RADIOGRAPH.

At a meeting of the British Institute of Radiology held on November 14th, Dr. James F. Brailsford read a paper on the significance of the dental radiograph and its interpretation.

Dr. Brailsford said that obscure foci of dental sepsis were found chiefly among patients seen in private practice, and that these suffered more frequently than hospital patients from neuritis, arthritis, obscure toxaemias, or other infective disorders. This fact he attributed to modern dental treatment. With the hospital patient,

when caries extended near enough to the pulp to produce pain, the tooth was extracted, and it was only when the tooth broke and septic stumps were left behind that local or systemic disturbances were likely to follow. Modern dentistry aimed at saving the teeth, and, providing that caries was detected early—and this could only be done with the careful co-operation of the patient and regular inspection by a dental surgeon—it was possible to remove the infected material and, by "stopping," to preserve the tooth in a healthy condition. If the lesion progressed until the pulp was infected there was no treatment which would definitely prevent the tooth becoming a possible source of toxin production, and no better or more economic treatment could then be applied than extraction. It was chiefly because such teeth were root-filled that the private patient was rendered more liable to toxic absorption. Root-filling of septic teeth was a very dangerous proceeding and had led to grave local or systemic disease and death. No matter how anxious the patient was to retain such a tooth, only extraction should be advised. It was because some patients were known to retain septic teeth for years without apparent harm that the danger of such teeth was not realized by the dental surgeon. Patients were fortunate in whom the breakdown of resistance to the infection was announced by nothing more serious than the onset of neuritis, the persistence of pain in an injured joint, or the development of painful movements in a joint subjected to strain. In the *British Medical Journal* (October 27th, 1928, p. 764) a well-known surgeon described his own severe illness which resolved after an antrum infected from the canine tooth had been drained. During the past year the lecturer had radiographed three patients, too ill to be moved from bed, with similar symptoms, and these had cleared after the septic teeth discovered by the radiograph had been extracted. The fact that cases of auricular fibrillation, retrobulbar neuritis, sinusitis, and other serious conditions had considerably improved or disappeared after the detection and removal of septic teeth pointed to the need for the prevention and early detection of apical sepsis. Septic teeth, Dr. Brailsford continued, might be detected by the patient, the dental surgeon, and the radiologist. The patient might not be able accurately to localize the painful tooth if the lesion was a pulpitis; and if, as sometimes happened, the pain ceased during the dentist's inspection, the latter might not be able to detect the inflamed tooth even after repeated attempts. As a rule, however, foci of acute inflammation could be detected by the dental surgeon. It was quite another matter with chronic sepsis localized at the apices of teeth having a dead pulp. Septic foci of a severe degree might exist without the slightest local symptom to the patient, and might elude the most skilful inspection or "clinical" tests. It was suggested that septic apices gave a definite apical impulse, but the lecturer had known this impulse to have been reported as present in teeth which had not given any pain in ordinary circumstances and which had appeared on the radiograph as normal. On the other hand, teeth which the radiographs had shown to have large septic processes at the apices—a fact which had been confirmed on extraction—had not been suspected even after the most carefully applied clinical tests. In some cases the teeth had been *x*-rayed by the dentist, and the radiological findings had been ignored. The fallacies of the *clinical examination* were shown by the frequent contrary opinions of different dental surgeons. One would advise wholesale extraction, another extraction of one or two teeth, yet another no extraction, in the same patient. Any focus of chronic sepsis in bone led to definite changes, which could be shown on a radiograph, in the bone surrounding the lesion. Particularly was this true in connexion with septic teeth; by placing the films in close contact with the teeth and the *x*-ray tube at a distance from which its rays were practically parallel, it was possible to obtain radiographic detail sharp enough to reveal evidence of any source of chronic septic absorption. Teeth which did not show changes on a good radiograph and were not painful were not the source of chronic toxic absorption. On the other hand, every tooth which was a source of chronic toxic absorption showed changes indicating this on the good radiograph. The radiographs might also provide, though not invariably, some useful additional information in the case of *acute* septic foci. The patient was protected, however, by the pain which caused him to seek the help of a dental surgeon.

Turning to the interpretation of the radiograph, Dr. Brailsford said that the most helpful information could be obtained when the radiography was done with care and by an impartial observer. The radiograph and its interpretation should provide the doctor with independent evidence of the state of the patient's teeth, particularly about conditions likely to have a bearing upon his health. They should help the dental surgeon to deal adequately with any lesion which might be present. If the physician called in to see a patient suffering from what appeared to be septic absorption, possibly from teeth, was told that they had already been examined and radiographed by the dental surgeon and reported to be sound, he was placed in a very difficult position. To suggest a further *x*-ray examination was to involve the patient in expense and to throw doubt on the dental surgeon's opinion. Not to do so might mean that the septic focus was missed. If later it was discovered by another physician the former advisers were held in disrepute. The doctor's recommendation of wholesale extraction was based on his experience that such treatment resulted in alleviation of certain symptoms. Equal success attended the extraction of only those teeth shown by the radiograph to be septic, and probably left the patient with most of his or her own teeth and consequently less liable to the digestive disturbances experienced by many edentulous patients. A radiograph might be so poor that the most experienced could not interpret it; on the other hand it might be good and convey little or no information except to those experienced in interpretation. A series of lantern slides illustrating the various pathological conditions of the teeth and jaws and errors of interpretation were then demonstrated.

In the course of a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, on November 8th, with the president, Dr. R. J. Rowlette, in the chair, a joint note by Drs. V. M. Synge and O'Grady on a case of staphylococcal meningitis was read. The patient had recovered from a prolonged staphylococcal meningitis following a boil on the jaw, and the authors mentioned their reasons for believing that the route of infection was the blood. The course of the disease and the treatment were described; complete recovery had ensued. Records of other such recoveries were mentioned, and the treatment of the disease was discussed, the authors commending the performance of lumbar puncture and the careful continued administration of an autogenous vaccine. The President approved the use in this case of small doses of vaccine, since in an acute condition such as this, whether of septicaemia or meningitis, large doses would probably hurry an unfavourable result, whereas the giving of such a small dose was quite safe. He had no doubt that the vaccine played a very large part in the recovery of the patient. He did not regard lumbar puncture in these cases as being of much value, though it undoubtedly relieved the symptoms for the time being. Dr. R. A. Q. O'Meara said that the spinal fluid in this case was turbid; it contained an abundance of cells, and staphylococci were easily recovered. It was interesting to note that although the fluid was turbid, it gave an absolutely negative *Boveri* reaction. Dr. O'Meara discussed the mechanism of infection of the meninges in the light of recent research. Dr. H. Quinlan pointed out the danger of meningeal involvement in all cases of infection of the skin of the face, the mechanism being a spreading venous thrombosis. Dr. E. T. Freeman read a paper on cardiac infarction; he explained the changes in the electro-cardiogram which might result from a cardiac infarct, and discussed their significance. He emphasized the importance of distinguishing the occurrence of an infarct from an attack of "angina pectoris" without massive infarction of the heart muscle. He recorded the case of a patient who had survived two coronary emboli, as well as a cerebral embolus, an acute colitis, and an attack of gall-stone colic.

Reviews.

CARDIOLOGY.

Recent Advances in Cardiology,[1] by Dr. C. F. T. East and Dr. Curtis Bain, is one of the latest additions to this well-known series. It will appeal more to the specialist than to the general reader, for a work of this kind necessarily dwells at considerable length on those aspects of the subject in which most advance has been made, scientific and medical progress being dependent on the successful application of the more exact but frequently complicated methods. This is a disadvantage, we feel; it is not possible to be certain at any moment where the past parts company with the present in circulatory disease as a whole, and since cardiology has been in the "melting-pot" for some years it would have been interesting and useful to have an authoritative pronouncement on the accepted basic principles of to-day. Even a careful study of this book leaves the reader in a maze of biochemical and electro-cardiographic detail set in the antiquated frames of the past century. We do not suggest that the book has few merits, rather we desire to point out the limits of its undoubted usefulness. The expert reader will find that the greater part of cardiology is dealt with, and that the bibliographies are uniformly good, probably the best in the English language. The general reader, who has not had the opportunity to think out his position in each of the many ramifications of cardiac pathology, will fail to discover a guiding thread, and will perhaps conclude that cardiology is still the mystical interpretation of precordial sounds and murmurs modernized by electro-cardiographic records. The critically minded clinician, on the other hand, realizes that the well-established facts of heart disease are few but simple, founded as they are on a good physiological basis. His attitude is not one of slavish subscription to the doctrine that the facts of medicine remain unchanged under our varying interpretation of them, and therefore he will find this book entertaining and stimulating.

It is impossible to attempt a discussion of the conclusions reached at each point, but one or two of the more important and debatable subjects can be briefly passed in review. A good chapter on the newly described clinical entity of thrombosis of the coronary arteries makes a very favourable impression, and is quite naturally followed by one on angina pectoris, regarded as due to an "acute deficiency in the coronary arteries." This is what is generally believed to-day; but it is difficult to see how the authors' tenet, "It is hard to understand how true angina can occur under . . . conditions of rest," is consistent with the persistence of true angina at rest after being induced by antecedent exertion. The book includes a good discussion of the mechanics of congestive cardiac failure, but the authors do not recognize the difficulty of the subject nor outline the essential facts, which are as follows. In the first place, blood collects in the venous system, where its pressure rises, while that of the arterial system remains unchanged; secondly, the circulatory rate is reduced. It is not known when the overfilling of the systemic veins takes place, and whether it is sudden or gradual. It is generally accepted, however, that in all cases of congestive failure the venous pressure is raised before death, though the evidence is far from complete, and is likely to remain so till it is demonstrated that venous pressure can be estimated with sufficient accuracy by simple clinical methods; but it has been shown by many observers that this pressure falls gradually as recovery from congestion progresses. The evidence relating to the circulatory rate is adequately given in this book. Now the factors which produce the rise of venous pressure in failure cannot be readily synthesized, for a diminished circulatory rate with an unchanged arterial pressure in no way entails it, the pressure dispositions not resembling those seen in the schema of the physiological lecture-table experiment. Moreover, since our physiological circulatory rates are widely different in exercise and at rest, we should expect a demonstrable change in venous pressure to occur, taking the form of a fall during exercise and a return to partial congestion afterwards; these changes are quite opposite to those postulated by the sponsors of the venopressor theory, and their occurrence is unsupported by the unsatisfactory experimental evidence available on venous pressure during exercise. Again, it is difficult to see how the addition of the whole of the blood in the arterial system to the much more capacious and distensible venous cistern could alter the tension in the latter, unless the venous system is endowed with vasomotor nerves. This subject seems to be worthy of detailed study in the wards, as a mechanical problem.

TREATMENT OF RHEUMATOID ARTHRITIS.

Dr. A. H. Douthwaite is to be heartily congratulated on his little book on *The Treatment of Rheumatoid Arthritis*.[2] He is undoubtedly right in differentiating "rheumatoid arthritis," if that is the name which is to be used for the condition, from infective arthritis and hypertrophic or osteo-arthritis. The trouble is that the designation rheumatoid arthritis has come to be applied to all three types of arthritis, and in spite of careful descriptions such as that given by Dr. Douthwaite, it requires a very considerable degree of clinical experience to distinguish between them. Osteo-arthritis is a manifestation of degenerative process in elderly people with which neither infection nor toxaemia has very much direct relation. Infective arthritis is the direct effect of focal infection, and clears up when this is removed. Rheumatoid arthritis, on the other hand, is a systematic disease with a marked diathetic factor in which arthritis is a prominent but not essential clinical manifestation. The author, in summing up, states, "There is strong clinical and laboratory evidence for the belief that rheumatoid arthritis is a disease of complex nature in the etiology of which disturbances of the sympathetic nervous system, of the thyroid and possibly parathyroid glands play an important part, sometimes in conjunction with, or resulting from, the absorption of bacterial toxins, sometimes independently of focal infection." Vague, perhaps—as he himself recognizes—but it is better to be vague than wrong. In the section on treatment he follows logically his exposition of etiology, pointing out that there can be no one specific remedy for such a disease. Climate and clothing are all-important in the early stages, maintenance of proper posture in the acute stage, and in the third stage (when sometimes, in spite of care, contractures occur) he advocates the more extended use of manipulation. He rightly points out, however, that this method of treatment requires much care and discrimination, and he is perhaps a little optimistic as to the success of this measure in the more acute stages of the illness. Finally, Dr. Douthwaite draws attention to the fact that without the greatest good will, perseverance, and patience on the part of the patient our best efforts are foredoomed to failure.

HYGIENE AND PUBLIC HEALTH.

Of the three works on public health before us the largest and most important is the second edition of Park's *Public Health and Hygiene*,[3] which, in its first edition (reviewed in our columns on September 24th, 1921) has become one of the standard textbooks on the subject in the United States. The editor, Dr. W. H. Park, is well known as the director of the Public Health Laboratories of New York City, and among the twenty-four contributors may be mentioned Dr. Josephine Baker (child hygiene), Dr. Eugene L. Fisk (personal hygiene), Dr. H. H. Goddard (mental defectives), Dr. Alfred Hess (vitamins), and Professor G. E. A. Winslow, whose reputations here as well as in their own country suffice to stamp the work as authoritative. The subject matter of the book is dealt with entirely from the point of view of the United States; very few references are made to British work,

[3] *Public Health and Hygiene.* Edited by William Hallock Park, M.D. Second edition, thoroughly revised. Philadelphia: Lea and Febiger. 1929. (6 × 9½, pp. xiv + 902; 123 figures. 9 dollars net.)

except in Professor Winslow's excellent chapter on air and health, where the investigations of Professors Haldane and Hill are given due consideration. Dr. Park himself contributes the chapter on bacteriology in its application to public health, and, as might be expected, deals in a thorough manner with immunization to diphtheria and scarlet fever. He believes that diphtheria toxin-antitoxin of the standard degree of neutralization may be issued in place of the Schick test toxin, a local reaction following on a subcutaneous dose of toxin-antitoxin being, in his view, equivalent to a positive Schick reaction. The mortality from diphtheria differs in its age distribution in London from that in New York; about 50 per cent. of the deaths in London occur in persons under 5 years of age, in New York the figure is 81.5 per cent. With regard to the enteric fevers, Dr. Park recommends inoculation of those unduly exposed to infection, including in this category not only soldiers, nurses, hospital attendants, and doctors, but travellers, persons in epidemic localities, and the families of carriers. Isolation of typhoid patients, he says, should be carried out in fly-proof rooms. He points out that in oyster-borne outbreaks contamination has almost always occurred after dredging, which indicates that oysters in their beds have a considerable natural freedom from pathogenic organisms, even in the presence of sewage pollution. Some facts about the American practice in relation to small-pox vaccination are interesting: in New York City the vaccine is made from human-calf-rabbit seed; vaccination is performed by making a single scratch not more than a quarter of an inch long through the drop of lymph, and, if possible, the operation has to be avoided during the months of July, August, and September. Some of the chapters, notably those on cancer and venereal diseases, are given added interest by the vivid style in which they are written; thus Dr. Soper states that more people die of cancer than are killed by railways, street cars, automobiles, fires, drowning, mining, accidents, machinery, poisons, homicides, and suicides all put together—surely a striking way of presenting bald statistics. By means of diagrams it is clearly brought out that in New York State, during the year 1925, venereal diseases headed the list of communicable diseases, and syphilis was three times as common as gonorrhœa. No fewer than twenty States have laws to prevent the marriage of persons suffering from venereal diseases, and in eight of these States satisfactory medical certificates are required before marriage is allowed. As might be expected, the problems of rural sanitation are much more serious in the United States than in this country. Some progress has resulted from the practice of touring the country in motor cars, the wayside farmer having been induced to improve his sanitation in order to attract lodgers. A full description is given of the forms of privy found most suitable in hookworm infested districts. Other subjects receiving detailed discussion are immigration and prohibition.

The authors of *Community Hygiene*[4] have aimed at giving to the American university student the information that will enable him to take a part in leading and guiding public opinion on health matters; in this aim they have succeeded well—moreover, they supply an excellent account of the activities of American public health workers and voluntary associations in dealing with the common diseases. Perhaps the best chapters are those on tuberculosis as a community health problem, and on the community attack on heart disease and cancer. The authors lay stress on the irreparable damage that may be done by quacks claiming to treat tuberculosis and cancer, and devote a useful chapter to proprietary remedies.

Dr. J. P. MODI, who has had ten years' teaching experience at Agra Medical School, wrote the *Elements of Hygiene and Public Health*[5] to conform to a syllabus laid down by an examining board, and has therefore drawn considerably on the standard textbooks of hygiene and tropical medicine. Two special chapters on Indian village sanitation, fairs and famine camps, written to help future subassistant surgeons, should prove invaluable to medical men engaged in public health work in India. The writer gives a vivid picture of certain Indian social customs which must contribute largely to the high maternal and infantile mortality rates. The mother, one learns, is not washed or given clean clothes for the ten days immediately following her confinement; the room is kept dark, the doors and windows covered with thick and heavy curtains, and every opening plugged; very often an open charcoal fire is kept burning in the room. The dai, who has a hereditary right to practise midwifery, puts on dirty clothes specially reserved for the occasion. Her conduct of the case is obviously responsible for the deaths not only of mothers from sepsis, but also of newly born infants from tetanus neonatorum and erysipelas.

O'Meara, F.R.C.S.Eng., etc. Third edition, revised and enlarged. Calcutta: Butterworth and Co. (India), Ltd.; London: Butterworth and Co., Ltd. 1928. (Demy 8vo, pp. xiv + 645; 74 figures. 10s. net.)

BIOLOGICAL APPLICATIONS OF PHYSICAL CHEMISTRY.

THE "Collection de Précis Médicaux" published by Masson et Cie has acquired a high reputation, and this reputation is well sustained by the latest volume, which deals with biological and medical physical chemistry,[6] and is written by Professor ANDRÉ DOGNON.

The subject is a difficult one, because physical chemistry is a relatively young science that has undergone a very rapid development in the last quarter of a century. Moreover, its application to biology can only be dealt with by a person who is thoroughly conversant with both sciences. Professor STROHL contributes a preface in which he points out that this field has been much neglected because few medical men possess an adequate knowledge of physics, and the physicists positively avoid biology. As he says: "The physicist is accustomed to move in a region governed by clarity and logic and is habituated to a language which borrows the exactness of mathematics, and he dislikes venturing on the treacherous ground of biological applications, where probability takes the place of demonstration and simple analogies are only too often the substitute for formulae." Professor Dognon is fortunate in possessing the rare combination of knowledge and interests that is necessary for dealing with his subject, and he has produced a short, clear summary of the more important biological applications of physical chemistry. It is clear that the author has deliberately aimed at reducing the mathematics employed to a minimum, and hence the text can be readily followed by those who are not mathematicians. The author treats his subject with a certain clearness, brevity, and elegance that is traditionally associated with good French works, and his volume can be recommended as an exceptionally good introduction to a subject which is difficult, but which is increasing in importance with great rapidity.

GREEK MEDICINE.

DR. A. J. BROCK has contributed to the Library of Greek Thought, edited by Professor Ernest Barker, a useful and readable volume entitled *Greek Medicine, being Extracts Illustrative of Medical Writers from Hippocrates to Galen.*[7] With twenty years' experience as a translator, especially of Galen, Dr. Brock has made practically all the translations for this volume, and has supplied a valuable introduction and annotations. The introduction draws an interesting parallel between St. Paul and Galen: both were Greek-speaking Roman citizens of a strenuous missionary type, intolerant of sects and of opposition, and often addressed their disciples in epistles, not infrequently of a highly polemic character. In his summary of Greek medicine in Rome, Dr. Brock remarks that if Erasistratus of Alexandria explained disease on much the same lines as

[6] *Précis de Physico-Chimie: Biologique et Médicale.* Par André Dognon. Préface du Professeur A. Strohl. Collection de Précis Médicaux. Paris: Masson et Cie. 1929 (5 × 7½, pp. viii + 310; 63 figures. Paper cover, 30 fr.; bound, 36 fr.)

[7] *Greek Medicine, being Extracts Illustrative of Medical Writers from Hippocrates to Galen.* Translated and annotated by Arthur J. Brock, M.D.Ed. London and Toronto: J. M. Dent and Sons, Ltd., New York: E. P. Dutton and Co., Inc. 1929. (Cr. 8vo, pp. xii + 256. 5s.)

modern osteopaths, the theory of death and treatment invented by Asclepiades in Rome resembles "the electronic reaction" of Abrams. Most of the extracts are from the Hippocratic Corpus or from Galen, but Thucydides's account of the plague of Athens in 430 B.C., which was probably typhus, short extracts from Plato and Aristotle, and longer ones on the interrogation of the patient and on anatomical nomenclature from Rufus of Ephesus are included. It is appropriate that this volume should be dedicated to the memory of Dr. Francis Adams of Banchory, by one who has piously followed his example in bringing the Greek classics within the reach of many to whom otherwise they would be closed books.

NOTES ON BOOKS.

THERE is no sign of any abatement of the flow of books on endocrinology, but the work on endocrinology and the related syndromes of the sympathetic[1] by Dr. A.-C. GUILLAUME strikes a new note in its form. Instead of considering the glands one by one, the author adopts the manner conventional in monographs on the nervous and cardio-vascular systems and considers the endocrine system as a whole. The theme of this compact and elegant little volume is the role of the endocrine system in the major functions of the body. Accordingly the part played by the various glands in the maintenance of mental and physical health, in excretion and reproduction, and the interplay between the old endocrine system and the new nervous system, are all fully considered. The book is a useful adjunct to the large and formal treatises, and we do not think there is anything quite like it.

Clinical Laboratory Methods[2] by Dr. R. L. HADEN, is a short textbook that aims at giving full working details of selected methods for performing the more important clinical tests. The work has evidently met a popular need, for it has reached a third edition in a few years. The present issue contains relatively few alterations. Certain tests which are seldom used have been omitted, and others have been added. The Kahn precipitation reaction for diagnosis of syphilis is the most important new test introduced in the present edition.

In a generously illustrated volume on *Growth*[3] five popular lectures, given by five professors of the University of Missouri, are reproduced; the lecturers being the professors of botany, dairy chemistry, agricultural chemistry, anatomy, and physiology. This fascinating subject is thereby approached from various aspects. Professor ROBBINS in his introduction clears the ground to some extent for Professor BRODY, who analyses the course of growth and senescence, processes which go on simultaneously, the difference being one of their respective dominance. Like the melancholy Jaques, he divides life into seven stages, beginning with the ovum after fertilization, then the foetal stage up to birth, the infantile, the juvenile from 3 to 12 years, the fifth of adolescence up to about the age of 23 years, the period of middle life between 25 and 50 or 60, and the seventh or last beginning after 60. Professor HOGAN deals with the relations between growth and nutrition, and Professor JACKSON with morphogenesis or the changes in the form of animals and their parts during growth and development, the complex factors determining these developmental changes being briefly discussed. This last problem is more fully considered in the final lecture on the physiological factors regulating normal and pathological growth by Professor C. W. GREENE, who gives many illustrations of the effects of endocrine disease on growth.

Those who wish to improve and vary their daily menus may be advised to study *Mrs. Lucas's French Cookery Book*.[4] She gives directions for the preparation of French dishes simply and economically, and writes with evident joy of the pleasures to be derived from a well-balanced and well-prepared meal. All that she demands from the cook in reproducing French methods is the taking of trouble, a sharp knife, and a few extra minutes' work. Her tastes are catholic; she commends Roquefort cheese, but admits that it must be good to be palatable. In fact, her only aversion (and we confess to sharing it) appears to be for venison, the cooking of which she declines to discuss. The choice, use, and care of wines are dealt with briefly by Mr. C. W. Berry and by an "Amateur of limited means." Many will agree with the latter that a glass of sherry with the soup is infinitely preferable to a cocktail before dinner, and that the apéritif, if used at all, should be taken a good half-hour before the meal. We like also Mr. Berry's blunt advice to Englishmen, "Never despise beer."

That "notes" may serve a useful purpose is proved by the call for a sixth edition of the notes[12] Mr. E. B. DOWSETT has been in the habit of giving the students of his tutorial classes for the final L.D.S. examination. As aids to memory, classification and tabulation are to many students invaluable, and in later life a glance at a comprehensive notebook may recall a forgotten condition and explain a mysterious case. Mr. Dowsett's notes will well serve these purposes. But random opening of the pages shows the dangers of the system. Under treatment of gangrenous stomatitis we find, "Excise ulcer and perform plastic operation"; "notes" do not permit of an elaboration of the limitations of this treatment. And what is the differential diagnosis, if any, between polypus of the gum and epulis? A short chapter on bacteriology by Mr. A. Bulleid adds greatly to the value of these notes, which many will find a most useful vade-mecum.

RECENT ADVANCES IN THE TREATMENT AND PROPHYLAXIS OF LEPROSY.

CAMERON LECTURE BY SIR LEONARD ROGERS.

THE following is an abstract of the Cameron Prize Lecture, which was delivered at the University of Edinburgh by Major-General Sir Leonard Rogers, C.I.E., F.R.S., on recent advances in the treatment and prophylaxis of leprosy.

The lecturer said the time was ripe for a review of the recent advances in the treatment of leprosy and their bearing on prophylactic measures to reduce the incidence of this ancient and dreaded disease. He estimated that it still affected some three million people in the world, and about half a million in the British Empire, the highest rates of incidence being found in our African tropical possessions, especially in areas with high temperature and humidity. The task of reducing leprosy was therefore heavy; it would never be accomplished by the mediæval method of compulsory segregation, with the inevitable hiding of patients in the early more curable stages of the disease. After spending three years in close study of the literature of the subject, which covered some sixty years, he had come to the conclusion that in 80 per cent. of the cases the infection was contracted by living in the same house with a leper, although only 3 to 5 per cent. of those so exposed contracted the disease: this showed that it was only slightly contagious. In 80 per cent. the incubation period was less than five years.

Evolution of Leprosy Therapy.

Among the more common and unsatisfactory methods of treating leprosy formerly might be mentioned local applications and surgical operations; the use of mercurial, copper, gold, arsenical, and antimony compounds; vaccines made from supposed cultures of the lepra bacillus and other saprophytic organisms, including nastin; tuberculin; sterile emulsions of leprotic nodules; and protein shock treatment; of all these it might be said that in no appreciable percentage of cases had they brought about lasting disappearance of all the active signs of leprosy. The fallacies of treatment were next pointed out, including those due to the variable course of the disease, and especially the spontaneous great improvement which temporarily followed the acute phase, and was likely to be erroneously attributed to any drug which happened to be given at that time. It was necessary to treat a considerable number of cases for long periods to enable any reliable conclusions to be reached.

The one ray of hope derived from a study of the older literature was the frequency with which slight febrile and local reactions, more particularly after vaccines, had often been followed by considerable temporary improvement; if a method could be devised of producing repeated slight reactions with a fair degree of certainty an advance should result. Potassium iodide had long been known to cause reactions of diagnostic value, and recently E. Muir

reported good results from this drug in doses of from 1 to 240 grains, but J. Lowe and Robert Cochrane had found it far more easy to do harm than good with this method.

The story was then related of how the old Indian remedy chaulmoogra oil was introduced to European medicine by Mouart of the Indian Medical Service in 1854, and its failure to do more than retard the progress of typical cases of leprosy, owing to its nauseating nature. In 1916, however, Ralph Hopkins in Louisiana reported success in clearing up a few early cases with oral administrations of the oil, thus indicating that it had some definite action. Moss in 1879 had separated the lower melting point fatty acids to which the name gynocardic acid was given; the oral administration of this product, the lecturer found, was more effective than that of the whole oil. In 1904–7 Power had separated chaulmoogric and hydnocarpic acids from both the chaulmoogra oil of Burma and the hydnocarpus oils of India and Indo-China. In 1914 Victor G. Heiser recorded promising results from prolonged and painful intramuscular injections of the Mercado mixture containing one-third of chaulmoogra oil; in the following year Sir Leonard Rogers, at Heiser's request, renewed his former efforts to obtain a soluble preparation of the active principle of the oils on the lines of his previous success with emetine, the active principle of ipecacuanha. He soon found that a solution of sodium gynocardate injected subcutaneously, although painful, was an advance on the oral treatment. In 1916 he discovered that this preparation could also be used intravenously with safety; slight febrile or local reactions occurred, accompanied by extensive breaking up of the bacilli in the leprous tissues, and followed by more rapid improvement and the ultimate disappearance of all clinical signs and bacterial infection in a number of comparatively early cases obtained from among hospital out-patients. Further repeated injections of this preparation produced gradual breaking up and disappearance of the lepra bacilli in nodules and the slow development of immunity, even when little or no evident reaction occurred, with eventual clinical cure and removal of all infectivity. In 1917 twenty-six cases treated for three months and upwards were reported, showing recovery in a number of them, and improvement in all but one. With the help of a chemist, Dr. Sudamoy Ghosh, chaulmoogra and hydnocarpus oils were fractionated and the soluble sodium salts of different melting point fractions were tried. As the result of several years' patient work it was established that the high melting point chaulmoogric acid fraction was useless, but the lower melting point hydnocarpic acid and the so-called gynocardic acid constituted the active parts of the oils, which could best be obtained from the seed of the *Hydnocarpus wightiana* of Southern India. Similar preparations were made from cod-liver oil, soya bean, and other oils, which were also of value in the treatment of leprosy, but they were not so active as the hydnocarpates. Of 51 cases of leprosy treated with the hydnocarpates and gynocardates for three months and upwards in the course of five years, 40 per cent. completely cleared up, and another 40 per cent. were greatly improved; and only one very advanced case showed no improvement. Nearly all the patients were treated by the intravenous method, which was more effective and less painful than the subcutaneous injections; it had the disadvantage of often causing blocking of the veins sooner or later, and was therefore more troublesome.

Meanwhile, in 1919, a useful modification of Sir Leonard Rogers's method had been introduced by Hollmann and Dean in Honolulu—namely, the less troublesome intramuscular injection of the ethyl esters of the whole oil in the form of a thin oily liquid; this preparation had for long been used with much success in Hawaii, at the Culion leper settlement of the Philippines, and by E. Muir in Calcutta. In 1925 E. Muir reported success following the subcutaneous and intravenous injection of pure fresh *Hydnocarpus wightiana* oil with 4 per cent. creosote as an antiseptic, which was less than one-twentieth the cost of a good ethyl ester. In 1927 the lecturer recorded the elimination of the vein difficulty by using sodium hydnocarpate. Dr. T. A. Henry prepared a substance—alepol—the sodium salt of the lower melting point fatty acids of *Hydnocarpus wightiana* oil, from which he had removed the irritant properties of Rogers's early preparations. Alepol was very effective, and painless, whether injected subcutaneously or intramuscularly; it could also be used intravenously in the few cases requiring this procedure by Muir's simple expedient of drawing up about an equal quantity of blood from the vein into the syringe which contained the dose, and then injecting the mixture. The cost of alepol was one-twentieth that of an ethyl ester, and it had been used effectively in many of the colonies during the last few years in several thousand cases.

The results obtained in the largest series of cases yet reported showed 41 per cent. of clinical cures by Rogers's intravenous method, and 31 per cent. by Muir's subcutaneous and intramuscular injections, both series being mainly composed of earlier hospital cases than those seen in leper asylums under the compulsory system. Dr. Isabel Kerr, in her leper hospital at Dichpali, obtained 17 per cent. to 19 per cent. cleared up, and 63 per cent. became bacteriologically negative and uninfective. The most extensive trial in 6,000 advanced cases of eight years' average duration on admission at Culion, reported on by H. W. Wade and C. B. Lara, showed from 15 per cent. to 20 per cent. clinical cures, with a total now amounting to over 1,000 cases. Thus it was clear that, as might have been expected, the results were much better in the case of persons in the early stages who had been attracted to voluntary clinics than in the patients with advanced disease who were obtained by compulsory segregation. The importance of finding the early stages was well illustrated by the results in 486 lepers treated at the Honolulu hospital during five years: these showed 8 per cent. of recoveries in very advanced cases, 38 per cent. in moderately advanced, and 64 per cent. in early ones. It was clear, therefore, that anything which led patients in the early curable stages to hide away, as was inevitable under rigid compulsory segregation, might in these days easily do more harm than good, and actually retard the reduction of leprosy. Yet, the lecturer added, in some colonies the more curable early bacteriologically negative lepers were not eligible for admission to the leper asylums until they had become infective and too advanced to have much hope of cure, no provision being made for their early treatment—a situation only defensible in the past when there was no effective treatment even of early leprosy.

Sir Leonard Rogers then discussed the necessity of modifying rigid compulsory segregation in order to attract the early clinically curable cases. He advocated the system already adopted in Mauritius, and about to be legalized in British Guiana—namely, that cases reported by an expert committee to be not infectious should be treated at clinics or at home, and not be imprisoned. No such compulsion was attempted in our tropical African possessions, yet some 5,000 new cases were attracted to voluntary clinics and colonies last year alone. In view of the facts already mentioned—namely, that 80 per cent. of leprosy was contracted by living in the same house as a leper, and that in 80 per cent. the incubation period was under five years—the lecturer submitted a scheme which provided that, as soon as a leper was found, all his household were examined for early cases; this was repeated every six months for five years. In this way some 80 per cent. of the probable infections from the case should be detected in the early stage; a considerable majority of the patients would be cured and prevented from becoming infective, with a corresponding reduction in the remaining foci of infection. Since patients with advanced nodular disease died in from eight to ten years, and the nerve cases became uninfective, by repeating this process for a second five years few infective cases would remain. A great reduction of leprosy would result within a single decade wherever this simple plan could be put into operation, as was now being done in a leprous area in one of our colonies. Thus the recently acquired power to clear up even the majority of the early cases of leprosy had for the first time in the history of medicine placed it in our power to reduce the disease with a rapidity hitherto unimagined. The recent advances in the treatment of leprosy should therefore be regarded as being by no means the least of the romances of modern medicine.

SURGERY OF THE BILIARY TRACT.

BRADSHAW LECTURE BY MR. R. P. ROWLANDS.

At the Royal College of Surgeons of England, on November 14th, Mr. R. P. ROWLANDS, Fellow of the College, delivered the Bradshaw Lecture, in which he reviewed the surgery of the gall-bladder and bile ducts. The lecture was illustrated by a number of specimens, including some very large or otherwise remarkable gall-bladders and calculi which had been removed by various surgeons.

History of Gall-bladder Surgery.

Mr. Rowlands stated that the surgery of the gall-bladder and bile ducts was only about fifty years old. In the early eighteenth century Petit suggested and described cholecystotomy, but the fear of peritonitis was so great that the operation was not actually performed until 1867, when J. S. Bobbs, as recorded in the *Transactions* of the Indiana State Medical Society, exploring for a supposed ovarian cyst, found and opened the gall-bladder and extracted about fifty small stones, afterwards closing the bladder and dropping it back; the patient recovered. In 1879 Lawson Tait successfully removed a large stone from the gall-bladder and a small one from the cystic duct, and ten years later he published a list of fifty-five cholecystostomies, with only three deaths. In 1885 Mayo Robson successfully performed his first cholecystostomy, and in 1892 published his stimulating book on gall-stones, in which he described six operative procedures: (1) cholecystostomy, or drainage of the gall-bladder, the operation of choice; (2) "ideal cholecystotomy," since abandoned as too dangerous; (3) cholelithotrity, or crushing of the stones, useful at a pinch, but crude, and apt to be followed by recurrence owing to left debris; (4) cholecystectomy, or removal of the gall-bladder, most generally successful for diseases limited to the gall-bladder and cystic duct; (5) choledochotomy, or incision of the common bile duct, and (6) cholecystenterostomy, or joining of the gall-bladder to the bowel. For many years only the serious effects of gall-stones were treated by surgery; but with increasing knowledge acquired from operations and the study of early symptoms, both physicians and surgeons now endeavoured to forestall these serious consequences, and even to prevent the formation of gall-stones, by eliminating the infection which almost constantly preceded it.

Anatomical Variations of the Parts.

The gall-bladder varied considerably in position and size, was occasionally double, divided, or absent, but frequently was either contracted or very large as a result of disease, and sometimes so adherent to important structures as to be difficult to define or unsafe to remove. The cystic duct was often long, running parallel with and adherent to the common hepatic duct, or, on the contrary, very short or absent. The so-called normal arrangement of the arteries was found by Flint in only 69 of 200 consecutive dissections. The relations of the vessels to each other and to the ducts were so variable that constant care was necessary to avoid mistakes which might lead either to severe bleeding or to the accidental tying of the right hepatic artery. Tying of the hepatic artery was a grave error which was found to interfere with the nutrition of the liver, and might lead to the death of the patient. These mistakes could be avoided only by keeping very close to the gall-bladder and its duct, by using gauze dissection, and by examining each vessel very carefully before it was tied and divided.

Diagnosis and Indications for Operations.

Simple radiography revealed the shadows of some opaque gall-stones and thick-walled or calcified gall-bladders. It should always be tried before cholecystography, because it might render this superfluous. With the aid of the opaque meal, radiography indicated pressure or traction of the distended or retracted gall-bladder upon the stomach, duodenum, or colon; but this method gave correct results only in about 30 per cent. of cases. Cholecystography, since its discovery in 1923, had been proved to have many merits and possibilities. Whereas simple radiography, even with the aid of the opaque meal, rarely gave any indication of cholecystitis or of small or non-opaque gall-stones, cholecystography assisted in an early diagnosis of all these, and was particularly useful in demonstrating obstruction of the bile ducts before cholecystitis had developed or become recognizable. It also enabled an estimation to be made of the power of the gall-bladder to concentrate and expel bile, and of the liver to secrete it. Graham and Cole, the discoverers of the method, preferred the intravenous administration of 2.5 grams of phenoltetraiodophthalein. Mr. Rowlands agreed that the test was a little more accurate when the drug was given intravenously, but it was more convenient and was often considered safer when given by the mouth. For oral administration Graham and Cole used 4 to 5 grams of tetraiodophenolphthalein. The dye ought not to be given to patients suffering from heart disease, atheroma, abnormal blood pressure, or to those affected with chronic jaundice, cholangitis, or threatened with uraemia or hepatic insufficiency. Otherwise the pure dye, given with care and in suitable doses, rarely did any harm.

The chief indications for operation upon the biliary tract were (1) obstruction of the cystic duct (as indicated by typical attacks of biliary colic with tenderness in the right hypochondrium, and often a palpable gall-bladder) or of the common bile duct (as indicated by recurrent attacks of biliary colic and jaundice, or increasing and persistent jaundice without colic); and (2) irritation and infection of the gall-bladder (as indicated by chronic flatulent dyspepsia, pain and tenderness over the gall-bladder, and cholecystographic evidence of disease or of stones). The mere demonstration of gall-stones or cholecystitis was not sufficient indication for operation, for in many cases they caused no appreciable discomfort, or only such as could be relieved by medical treatment. When symptoms persisted or recurred in spite of medical treatment, it was generally wise to recommend early operation so as to prevent a high mortality and other serious consequences of delay, of which Mr. Rowlands gave a long list. These included cancer of the gall-bladder, which developed, according to Rolleston and others, in at least 5 per cent. of all cases of gall-stones, and the danger even of this one complication was greater than that of operation.

When possible, it was safer to wait for a quiet interval before operating, so as to allow thorough investigation and preparation of the patient. When signs of spreading peritonitis developed, or an enlarged, tender gall-bladder could be felt, and symptoms such as vomiting, fever, and rigors did not abate, or signs of acute pancreatitis appeared, an immediate operation was necessary. Similarly, when jaundice, associated with fever, failed to clear up under medical treatment, an early operation afforded the best hope. These emergency operations should be limited to simple drainage of the gall-bladder or common bile duct. Radical operations could be carried out later when the patient was better, the liver function restored, and the sepsis subsided.

Preparation for and Technique of Operation.

The patient was kept at rest, preferably in bed, for two or three days and dieted. Plenty of sugar and glucose and sodium bicarbonate were given by the mouth, rectum, or even intravenously in all cases where failure of the liver functions was feared. Hexamine was given as a biliary antiseptic. All septic sources in mouth, nose, and throat were treated in time to lessen the risk of pulmonary complications. When the patient was jaundiced, and clotting of the blood was delayed, 5 c.cm. of a 10 per cent. solution of calcium chloride was injected intravenously for two or three days before the operation, or, if this failed, transfusions of blood might be given.

With regard to anaesthetics, chloroform was best avoided, on account of its destructive effects on liver cells. An injection of 1/4 grain of morphine and 1/100 grain of atropine was given forty-five minutes before the operation. Ether and oxygen were administered, gas and oxygen rarely affording enough muscular relaxation. Novocain injected into the free edge of the lesser omentum and near the neck of the gall-bladder lessened shock and increased relaxation.

For bad subjects, twilight sleep, followed by local anaesthesia, sufficed, especially for simple operations. Spinal anaesthesia with a little gas and oxygen was also valuable.

Mr. Rowlands found that Kocher's incision, which divided the whole width of the rectus muscle and its sheath one inch below the right costal margin, gave the best access for cholecystectomy in fat and muscular patients. The right paramedian incision gave the best access to the lower part of the common bile duct, to the pancreas, and to the appendix adherent low down in the abdomen or pelvis. A stab wound for drainage allowed the paramedian incision to be completely closed to lessen the chance of ventral hernia. For secondary operations, a fresh site for the incision was generally desirable, so as to avoid adhesions and allow a free exposure with less risk of damage.

The abdomen having been opened, the surgeon, whenever possible without adding to the patient's risk, rapidly explored the whole abdomen to discover and remove any source of sepsis. In many cases it might be necessary to remove a diseased appendix. The gall-bladder and bile ducts were examined with the greatest care. It was important to remember that stones might rest in the common bile duct for years without causing jaundice. Mr. Rowlands mentioned that at his first cholecystectomy the gall-bladder contained ninety-nine small faceted stones, which he removed, but he overlooked the hundredth, which was in the common bile duct, and this caused frequent attacks of colic, without jaundice, until he removed it also four years later. When the common bile duct was dilated, especially with the gall-bladder present and active, the ducts must be palpated with extreme care, and often it was necessary to open the common bile duct and examine the passage from within.

Disease Limited to Gall-bladder and Cystic Duct: Procedure.

When the disease was limited to the gall-bladder and cystic duct the choice lay between cholecystectomy and cholecystostomy. Removal was far better than drainage, for the following reasons: drainage rarely cured cholecystitis because the infection lurked deeply in the walls of the gall-bladder; a diseased gall-bladder, being the chief factory of gall-stones, was better removed to prevent recurrence; it was difficult to ensure removal of all the stones, and often easier, cleaner, and therefore safer to remove the gall-bladder and cystic duct without opening them, and, finally, excision of the gall-bladder might get rid of an unsuspected early cancer or pre-cancerous condition. The gall-bladder was not indispensable, and although it had been shown to have several interesting functions, certain animals, such as the horse, deer, and rat, had no gall-bladder, and thousands of human beings who had had it removed got on well without it.

The chief indications for cholecystectomy were irreparable wounds and injuries or diseases limited to the gall-bladder and its duct; among the most important were acute, chronic, and recurrent cholecystitis, typhoid infection, gangrene, perforation, empyema, or fistula of the gall-bladder, due to obstruction of the cystic duct by stone, torsion, kink, band, or stricture, fibroma, adenoma, papilloma, or carcinoma, and biliary fistula or chronic jaundice due to kinking of the common bile duct following cholecystostomy.

It was not wise to undertake cholecystectomy when the patient was very ill, old, or feeble, or when the mechanical difficulties and dangers of the operation were too great for the operator. Cholecystostomy was safer under the circumstances, care being taken to remove all the stones if possible. If the symptoms recurred secondary cholecystectomy should be performed in more favourable circumstances. Nor should cholecystectomy be attempted when there was chronic jaundice with consequent risk of haemorrhage, unless the normal coagulation time had been restored by treatment, nor when there was infective cholangitis or hepatic insufficiency. Cholecystectomy should never be performed unless it was certain that the common bile duct was patent. It was easy enough to recognize gross disease of the gall-bladder, but slight abnormalities were frequently overlooked. If the clinical history and examinations, especially cholecystography and the finding of bacteria in the duodenal bile, incriminated the gall-bladder, it was generally wise to remove it, although it might not look abnormal.

Affection of the Common Bile Duct.

When the common bile duct was affected, obstructive jaundice generally followed, often due to stone in the duct, carcinoma of the head of the pancreas or bile duct, or chronic pancreatitis. When jaundice was associated with colic it was generally due to impaction of stone or other foreign body in the common duct. It was far better to remove the obstruction if possible than to make a short circuit between the gall-bladder or bile duct and the stomach or intestine. A stone impacted in the lower part of the common bile duct was best moved back into the first part of the duct and held there before the latter was opened; when impacted at or near the duodenal papilla, the transduodenal route was good and safe. Whenever the first or second part of the common bile duct had been opened it was his practice to insert a tube for drainage.

If the jaundice was due to chronic pancreatitis or carcinoma of the head of the pancreas, he preferred cholecystogastrostomy to any other treatment. It was much better than draining the gall-bladder or common bile duct to the surface of the skin, and it appeared to be easier, safer, and better to drain the distended gall-bladder into the stomach than into the duodenum or small or large intestine. Chronic pancreatitis, with jaundice, was generally cured by cholecystogastrostomy.

Reconstruction of the bile ducts was required occasionally after excision of growths, but more commonly after accidental injuries during operation. It was better to make the necessary repair immediately, before inflammation had changed and confused the anatomical appearances, and before ascending hepatitis and hepatic insufficiency had developed.

Results of Operation.

The death rate of operations upon the gall-bladder and common bile duct was surprisingly low, considering the complicated nature and difficulties of the procedure. Graham and his colleagues, in their last 309 cholecystectomies for both acute and chronic cholecystitis, with or without stones, had a mortality of 2.8 per cent. Eleven cholecystostomies—performed only in cases which were the worst risks—had a mortality of 18 per cent. The lecturer gave his own figures, mentioning that, as observed by Wilkie and others, mortality was higher in private patients, who were apt to wait too long and to try various treatments before operation. Between July, 1916, and January, 1929, 251 operations for gall-stones and cholecystitis were done in his wards at Guy's, with 7 deaths—a mortality rate of 2.8 per cent. During the last ten years he had operated upon 175 private patients for all kinds of diseases of the gall-bladder and bile ducts, with 11 deaths—a mortality of 6.3 per cent. Five of the deaths occurred in the 25 of these cases in which choledochotomy was done, the death rate here being naturally higher because the patients requiring the operation were often bad subjects, who had suffered for years and develop

As for the ultimate results, complete and permanent relief of symptoms in only about 45 per cent. of cases. Persistence or recurrence was often due to leaving stones behind, to inflammation continuing in the walls of the gall-bladder, or to formation of new stones. Cholecystectomy afforded complete and permanent relief in about 86 per cent. of cases. Some temporary recurrence of symptoms, as Hurst had pointed out, might follow cholecystectomy, owing perhaps to spasm of the sphincter of Oddi with dilatation and other changes in the bile ducts, secondary to the loss of the gall-bladder. Medical treatment would generally cure these symptoms, and should be well tried before the patient was submitted to another operation. Persistence of symptoms after operation might be due to residual infection in liver or pancreas, to overlooked stones, to errors in diagnosis, to osteo-arthritis of the spine, or spastic or mucous colitis. But the results of operation might be said to be extremely satisfactory and to compare favourably with those obtained in any other branch of surgery.

Nova et Vetera.

ARCHAEOLOGIA MEDICA: THE ICONOGRAPHY OF AMBROISE PARÉ.

I have recently received the following letter: "A week or two ago Mr. C. J. S. Thompson sent me a photograph of the portrait of Ambroise Paré which Lord Moynihan has just presented to the Royal College of Surgeons of England. Mr. Thompson says that he came across the original, which is attributed to Miereveldt, at Fécamp last year. Lord Moynihan commissioned an artist in Paris to copy it, since it is believed to be the finest portrait of Paré now extant." The portrait is here reproduced from a photograph. As Dr. C. Hofstede de Groot, the late director of the print room at the Rijksmuseum, points out, the collar, the clean-shaven cheeks, the form of moustache, and the cap are indications that the picture was painted after the first quarter of the seventeenth century. Paré died in 1590, and it cannot, therefore, be a contemporary portrait.

Ambroise Paré.

The receipt of the letter reminded me that an iconography of the great surgeon has long been overdue, and should be undertaken by some competent French surgeon. As a beginning, I have examined the portraits which are in the possession of the Royal College of Surgeons and the Royal Society of Medicine. I have also consulted the admirable works of Malgaigne, Stephen Paget, and Dr. Francis Packard, each of whom has written a Life of Paré.

The portraits arrange themselves into three main groups. The first are oil paintings which are likenesses; the second are copperplate engravings or woodcuts; the third are what may be called fancy portraits—Paré idealized, or as he ought to have been, not as he was.

There are two paintings in the first group: (1) The unsigned portrait which in 1897 was in the possession of the Marquise Charron, whose husband was a direct descendant of Catherine Paré, the surgeon's daughter (d. 1659), who married Claude Hedelin, the advocate (d. 1638). This portrait is reproduced by both Paget and Packard, and is dated 1575. It represents Paré in his seven-buttoned surtout, with a small ruff and a cloak over the left shoulder. (2) The Fécamp portrait, which is here shown. It represents Paré as a younger man, with a square beard instead of the pointed one he usually wore. He has on a skull-cap and a wide linen collar in place of a ruff.

There was a third painting in the Ecole de Médecine at Paris, bought in 1852, and carrying the inscription in a circle: "Ambroise Paré. An. Dom. 1570. Aet. 56." He was pointing to a cloudy sky where the word Jehovah was written in Hebrew characters. When the picture was sent to be cleaned it was discovered that Paré was a modern superposition on a portrait of Tagliacozzi. The details about this portrait are given by Dr. Noe Legrand in the *Bulletin de la Société française d'Histoire de la Médecine*, 1909, tome viii, pp. 372–383.

There are many busts of Paré in the second group as copperplate engravings and woodcuts. The earliest is a copperplate in a square border with the inscription: "Labor omnia vincit. A.P. An. Aet. 45. R." It appears in the *Anatomie Universelle*, published in 1561. Packard has reproduced it in his book. This engraving, as a woodcut in a circle to form a medal, appears in the *Deux Livres de Chirurgie*, issued in 1573. The same motto is on the exergue, and below is the inscription: "A.P. An. Aet. 55."

Vallée drew a bust to illustrate the author's final edition of the complete works in 1585; Giullis Horbeck based his bust upon Vallée's work and issued it in 1607. Vallée's bust was made during Paré's lifetime. It must therefore have been a tolerably good likeness, as it was passed by his family and probably by Paré himself.

Of the fancy portraits, undoubtedly the greatest and the most pleasing is the heroic statue made by David of Angers for the town of Laval. It was unveiled on July 29th, 1840, and is certainly a masterpiece. An engraving of it by Petit appears as a frontispiece to Malgaigne's edition of the complete works. David also designed a bronze medal of the head. It is dated 1835 and has been engraved. A less pleasing study is the portrait by Robert Fleury representing Paré writing with his hand resting on a skull.

Such are a very few facts about the iconography of Ambroise Paré. There is much still to be done. Many of the engravings assign the surgeon's age. Some of these dates are clearly incorrect. Why were they given at all?

One whole group of the busts are characterized by a cloak over one or other shoulder; which of them is the original? Where did Cecill obtain the portrait which is best known to English readers, for it occupies the centre panel in the frontispiece of both editions of Thomas Johnson's translation? There are two editions at least of this portrait, each with the distich—

> "Humana Ambrosii vera haec pictura Paraci
> Effigiem sed opus continet ambrosiam,"

but in one the last word "ambrosiam" appears in Greek letters, and the engraving is signed "Joan. Heroaldus. In effigiem Ambrosii Paraei, Anno, Aetatis 68," so it is probably the first one.

These and many other questions arise, and it would be doing a service to surgical iconography if a thorough investigation were made of the whole subject. Such notes as I have are at the disposal of anyone who will undertake the task.

D'Arcy Power,
Honorary Librarian to the Royal College of Surgeons of England.

The *Medical Art Calendar* for 1930 has now reached us from Holland, and once again nothing but high praise can be given to it as a most attractive collection of paintings, engravings, and etchings relating to medical topics. These illustrations can be easily detached and framed separately, and the calendar itself is designed to lie on the desk or hang on the wall. A special album is being prepared in which illustrations appearing in previous calendars can be kept, and the pictures appearing in each calendar for the past eleven years can still be obtained, arranged in albums, for 8s. 6d. each, post free. The price of the *Calendar* for 1930 is 6s.; it may be obtained from Mr. J. P. Kruseman, Noordeinde 91, The Hague, Holland.

TRAINING AND EMPLOYMENT OF MIDWIVES.

Obstetricians and the Departmental Committee's Proposals.

The recent report of the Departmental Committee on the Training and Employment of Midwives was the subject of discussion, on November 15th, by the Section of Obstetrics and Gynaecology of the Royal Society of Medicine.

Dr. Arthur E. Giles, who presided, said that it was unusual for the Section to have a discussion on a non-scientific topic, but the matter was of the greatest importance to everyone connected with the practice of midwifery in this country. The view of the council of the Section was embodied in certain resolutions.

Dr. Herbert R. Spencer said that the report, a document of ninety-six pages, was signed by all the members of the Committee, except for the reservations made by Dr. Fairbairn and Mrs. Bruce Richmond, who dissociated themselves from the majority in regard to the recommendations which involved the splitting up of the functions hitherto exercised by the Central Midwives Board and their distribution between a reduced Board, the Ministry of Health, and an advisory committee. Parts II, III, and IV of the report, dealing respectively with maternal care, training of midwives, and employment of midwives, would, he thought, carry the assent of the Section. The historical survey in Part I mentioned the pioneer work of the Obstetrical Society of London, the forerunner of the Section, in laying down rules of practice and conduct, instituting a voluntary examination for midwives, and issuing a diploma guaranteeing that its possessor was a skilled midwife. The report might well have pointed out that it was due to the persistent efforts of the Obstetrical Society that the Midwives Act, 1902, was framed. The first rules and regulations of the Central Midwives Board were not only "no doubt largely based on"—as the report said—but in many cases were identical with those issued by the Obstetrical Society. Apparently, judging from the character of such criticisms as were made, the Departmental Committee did not find much amiss with the present rules and regulations of the Board. Part V dealt with administration, and here the committee made proposals for the diminution of the Board, the limitation of its functions, and the assumption by the Minister of Health of the sole responsibility for approving and inspecting training institutions and teachers, and laying down lines of curriculum. He hoped the Section would express its disapproval of these proposals on the ground that the Board was an expert body, which had performed its functions well in the past, and that its duties should not be handed over to the Ministry of Health, whose treatment of the panel doctors of England under the National Insurance Act was characterized by the Lord Chief Justice as pure despotism.

Dr. Watts Eden said that the report of the Departmental Committee contained a great deal with which all obstetric teachers would be in agreement. Serious exception must, however, be taken to the administrative proposals. The principle upon which the practice of midwives in this country had been governed since the first Midwives Act was passed was that there should be a statutory *ad hoc* authority appointed for the purpose, in whose hands were placed all matters relating to education and training and professional conduct. That was a sound principle, from which the Departmental Committee proposed entirely to depart. On the statutory authority midwives, obstetric teachers, medical officers of health, and general practitioners were all represented, so that the affairs of the midwives were in the hands of those who knew something about them. He would not affirm that the constitution of the Board was quite ideal, it might have been made more widely representative of the classes chiefly interested, and might have been given greater power, but within the limits imposed upon it by the legislature it did very excellent work. It was now proposed to deprive it of its most important function—namely, its responsibility for the training and education of midwives, which would be vested in the Ministry of Health, with the assistance of an advisory committee. Experience showed that advisory committees of Government departments were not allowed to do very much: an instance in point was the advisory medical committee appointed under Lord Dawson's chairmanship at the time the Ministry of Health was instituted, which had been given no serious work at all. The practice of the Ministry was to appoint committees of inquiry independently of its own advisory committee. If the advisory committee now proposed were ever asked for its opinion it was not known whether the Ministry would accept the advice given. This matter had to be considered in connexion with the scheme also adumbrated in the report for the foundation of a national maternity service. It was contemplated by the Departmental Committee that when this scheme was put into operation four-fifths of the confinements in this country would be carried out by midwives, who would be paid for their services by the local authority under the Insurance Act, and would consequently be to a great extent in the hands of the Ministry of Health. Midwifery would thus pass largely into the control of a Government department instead of being, as it was now, in the hands of the profession, guided by the statutory authority appointed for the purpose. Such a change could not be carried out without detriment to the teaching of midwifery and its practice also. One of the important duties of the Central Midwives Board was the approval and inspection of institutions in which midwives were trained. True, this prerogative had been interfered with by the action of the Ministry of Health, which, when Poor Law institutions began to train midwives, refused to allow the Board to inspect them on the ground that they were Government institutions. The Ministry said it would inspect them itself, but the Ministry had no inspectors on its staff capable of inquiring into the methods of instruction given in the schools. The structural features of the building might be inspected, and the suitability of accommodation for pupils and nurses, but the Ministry was not in a position to carry out the inspection required to certify any given training institution as efficient. To transfer these powers from an *ad hoc* authority to a Government department was a retrograde step. The authority appointed for the purpose should retain its powers, and should be enlarged and made more influential than the old Central Midwives Board and be given greater powers. The majority of its members should be drawn from those who knew from a practical point of view what the practice of midwifery was, while other members should be those whose experience of affairs would be advantageous from the point of view of organization. But an *ad hoc* authority there must be if anything like liberty was to be preserved. Before long there would be another scheme by which doctors who practised midwifery under the National Insurance Act would also become officials of the Ministry of Health, and paid by the State. The whole practice of midwifery, except for the fraction representing the classes to whom expense was no object, would pass into the hands of the Ministry, just as the treatment of infectious diseases had done. The sooner the profession made itself heard the better. The present resolutions were the first step—not the last—in making it clear to the Government that the Departmental Committee's proposals were unacceptable.

Dame Louise McIlroy said that what interested her was the future of obstetric teaching. If, as Dr. Eden said, four-fifths of the confinements in the country were to be attended by midwives, would the remaining fifth be in the hands of specialists or general practitioners? The teachers would agree that they were not out to teach the specialists; most of them were engaged in teaching the future general practitioners, and if the future practitioner was to have no opportunity to engage in midwifery it was quite time the medical schools saved the money they spent on teachers and on instruction. The chairman had apologized for the unusual nature of the discussion. She thought, on the contrary, that it was a great pity these questions of administration had not been taken up long ago. The Section had not done well to be so scientific as to keep itself outside the maelstrom of this controversy. This was a serious question from the point of view of the teaching schools and the future general practitioner. It was stated that the general practitioner of the present generation

was not interested in midwifery and ante-natal care. But certainly the future practitioner was being trained in these directions. She wondered what type of person in the Ministry would control these proposed arrangements. There might be people in administrative positions who understood the subject of midwifery, but knew nothing about clinics or the practical difficulties of the obstetrician. The midwifery service had been most efficient because it had had the benefit of teaching by specialists, a work which began in the old Obstetrical Society, and now the Ministry of Health were stepping in and taking advantage of all that training. She had a certain amount of sympathy with the Government because it did the paying, but it seemed likely that all midwifery would come under a Ministry of Health scheme, except for attendance on West End ladies who could afford specialists.

Dr. J. S. Fairbairn, one of the members of the Departmental Committee, invited by the chairman to speak, said that the difficulty he felt was to keep himself under control. He read a quotation from a Sunday paper reviewing Lord Hewart's book: "The conclusion is irresistible that it is manifestly the offspring of a well-thought-out plan the object and effect of which are to clothe the department with *despotic powers*"—*in this case over the midwives and midwifery generally*. He wanted to remind the Section what a departmental committee was. The word "departmental" was the clue to the whole thing. The department suggested what was required, determined the composition of the committee, appointed its chairman and its members. A member did not know what sort of folk he was going to sit with until the list was published, and he had found himself serving on "rather a comical body." The thirteen members included seven doctors, and among those seven the administrative side had the majority; there were three medical officers of health and an administrative officer of the Ministry, as well as, among the non-medical members, an assistant secretary. It was a "very mixed batch." Departmental committees, unlike Royal Commissions, did not publish their evidence: they chose what they liked. No one could tell, on reading the report, whether it was based on evidence or not. Much of the evidence given—hear-say and opinion—would not be admitted in a court of law. Further, the report was made to the Minister in charge of the department, who could publish it or not, as he liked; there had been a recent instance of a withheld report. On this committee "there was a distinct hostility towards the Central Midwives Board, and one rather felt that it was judged beforehand, but that is merely an impression." The suggestion for the administrative proposals came from the London County Council at a late stage of the proceedings. Dr. Fairbairn said he hesitated to go on because the *British Medical Journal* rather questioned the propriety of some of the things said in the reserved report. But the Ministry of Health had interfered constantly with the Central Midwives Board before ever he himself had anything to do with the latter, and withdrew the Poor Law hospitals entirely from its purview. That was the sort of thing that happened when a Government department had got hospitals under it; it gave them a privileged position. He had felt strongly that he would have nothing to do with inspection of training schools under the Central Midwives Board unless he could inspect them all. When the Board did get a certain amount of control over the Poor Law hospitals it discovered that some extraordinary things were allowed to go on. There were places where there were about thirty confinements in twelve months, and nurses engaged in staff nursing in the medical or surgical wards were hurried round to another part of the building when a confinement was imminent in order that they might look at it and sign it up for their certificate. That was being trained in obstetrics! For the rest, the proposals were the old idea of circumlocution—the Ministry would circumbcute the Central Midwives Board, and the Board would circumlocute the Advisory Committee, and the Advisory Committee again the Ministry. The process would begin by swallowing the midwives, and sooner or later the medical profession, so far at any rate as attendance on insured women under these new schemes was concerned. He hoped the resolutions would be accepted, for they were in the true spirit of the old Obstetrical Society, of which the Section was the lineal descendant.

Dr. F. H. Oxley said that he happened to be a member of another departmental committee (on maternal mortality), which was very happily constituted and functioning. The question now under discussion profoundly affected maternal mortality, and he believed the Section of Obstetrics and Gynaecology had been asked to give evidence. He did not know what the position would be if the Departmental Committee on Maternal Mortality reported in an exactly opposite sense to the Departmental Committee on Midwives. He could only say that all the members were extremely anxious that something should be done of real value, and they would consider from an unbiased point of view whatever the Section placed before them.

Dr. James Young hoped the Section would be able to persuade Dr. Oxley as to the justice of its cause. Evidence was accumulating from various sources that the conclusions to which the Departmental Committee on Midwives had come with regard to an alteration in the position and functions of the Central Midwives Board were wholly misdirected, and the fact that there had been a strong representation of the case in the *British Medical Journal*, and also to some extent in the *Lancet*, should carry a good deal of weight in converting those in authority who had to make the final decision. There was nothing which would militate against the raising of the standard of the midwife more than an attempt to undermine the interest and control which the professions concerned could take in the administration of their own affairs. He had indirect evidence that some members of the committee on which Dr. Fairbairn sat had become very shaky about the conclusions arrived at. On the other hand, Dr. Young hoped that this question of the midwife would not be allowed to entangle the bigger issue of the maternity service.

The President (Dr. Giles) explained that the resolutions had not been drafted in any spirit of trade unionism, with an idea of serving the narrow interests of the medical profession. Many members of the profession would, indeed, be only too glad to be relieved of this the most arduous and worst-paid part of their work. But it was felt that if the practice of midwifery were taken away from the present form of supervision and vested in a Government department, the well-being of lying-in women and newborn children would be seriously imperilled. He added that the resolutions would not go directly to the Ministry of Health, but would go first to the Council of the Royal Society of Medicine for its approval.

TESTIMONIAL TO SIR RONALD ROSS.

Seventh List of Contributors

We now print a further list of those whose donations were received between September 12th and October 31st in response to the appeal on behalf of the Ross Award Fund published in the *British Medical Journal* of May 11th. The total amount in hand at the end of last month was £10,279 13s. 10d. The list published below does not include anonymous contributors or those whose initials only have been supplied. Donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15.

Dr. Peter Abercrombie, W. Allard, *Mohamed Aziz Effendi*.
Mrs. Bull, Mr. D. S. Bruce, Mrs. Southorn, and Mr. M. K. Lo per the *Hongkong Daily Press*, Ltd., A. Chester Beatty, J. S. Brigg.
Sir Francis Champneys, Bt., M.D., Dr. J. F. Christie, Cairo (Malay) Rubber Syndicate, Ltd., Mrs. E. N. J. Cumming, Mrs. C. A. Clark.
Dr. Seymour W. Davis, Arthur H. Dodd, G. A. Duncan, Lieut.-Colonel C. L. Day.
Mrs. A. G. Foley.
E. S. Good, Miss E. Greaves, Mr. and Mrs. Gray, A. M. Gomall, Miss Evelyn Gardner, James Gordon.
Dr. Habgood, Miss Augusta Hughes, Miss Hudson and Miss Waitt, Mrs. A. Hassell, Mrs. V. E. Humphries and S. V. Humphries, High School for Girls, Queenstown, South Africa.
Mrs. M. E. Irvin.
M. K. Jameson, Jokai (Assam) Tea Co., Ltd.
Joseph N. Kong, King's High School for Girls, Warwick.

SATURDAY, NOVEMBER 23RD, 1929.

THE GYNAECOLOGIST IN THE MAKING.

Diversity of opinion still exists about the precise relation of gynaecology to obstetrics on the one hand and to abdominal surgery on the other, and the type of training best fitted for those intending to practise it as a specialty. Within its commonly accepted limits the sphere of gynaecology includes the diseases of the female reproductive tract, and the boundary between it and surgery, following the anatomical line of the tract, is fairly clear-cut, although it may be transgressed sometimes where the pelvic urinary and digestive tracts come into close relation with the reproductive tract. There is not, however, and there cannot be, any such clear differentiation from obstetrics, for the scientific basis of both gynaecology and obstetrics is the same, and their separation in practice is wholly artificial, being determined by custom, convenience, or method of treatment. No ruling or formula in words can be given that would decide what should fall into one or the other. Examples of a few incongruities may be mentioned. Pregnancy clearly falls to the obstetrician, but ectopic gestation is claimed by the gynaecologist; the acute puerperal infections are left to the obstetrician, while other acute infections of the female genital tract and all chronic infections fall to the gynaecologist, and septic abortions may be shared between the two; immediate injuries of parturition come under the one, and late injuries and their more remote results under the other. Even Caesarean section may not be disdained by the gynaecologist; and so the list might continue. These instances show that although practice may be divided into two portions, the science on which it is based cannot. That science comprises the anatomy, physiology, pathology, and hygiene of the female reproductive apparatus, together with certain related facts in endocrinology and psychology; and training on a broad foundation, with clinical experience in all these aspects of the subject, is essential to a proper comprehension and practice of any one of its divisions, more particularly of that division in which the injuries, infections, and diseases consequent on abnormal reproduction form so large a part of the clinical material.

In this country and in Germany the essential unity of obstetrics and gynaecology has been maintained, in science and in practice, and both are represented equally in the training of those devoting themselves specially to their study. In the United States the tendency has been towards the divorce of obstetrics from gynaecology, not only in practice, but also in training, seeking compensation by taking in urology and otherwise extending the sphere of gynaecology beyond its real frontiers. The American point of view was ably set out by Professor Thomas S. Cullen of Johns Hopkins University in a paper read at the recent Annual Meeting of the British Medical Association at Manchester, and published elsewhere in this issue of the *Journal* (p. 941). This paper was followed by a discussion[1] in which the British position was strongly upheld by the subsequent speakers. Professor Cullen's plea that the gynaecologist must be prepared to deal with any condition that he may meet in the abdomen received general acceptance, and his further points will not be questioned in regard to the need for a thorough training in abdominal surgery and for the gynaecologist to keep himself abreast of such procedures as he may occasionally be called to perform upon the intestinal or urinary system. From his paper it would appear that the sphere of the gynaecologist may extend from the pelvic outlet up to the dome of the diaphragm, so long, we suppose, as the abdomen is of the female gender; for surely, even in the United States, the gynaecologist must maintain his sex-linked character. As was pointed out in the discussion, manual skill is of less importance, and certainly is more easily acquired, than sound judgement and good diagnostic ability and the attitude of mind that may best be developed by a wide clinical experience of women throughout the reproductive period of life. There is a less obvious and more imponderable element than technical skill which Professor Cullen left untouched. The gynaecologist must be something more than a surgeon with a specialized knowledge of the pathology and treatment of pelvic disease; he should have a far deeper understanding of womankind, with its specific characteristics other than diseases, than can be expected of those whose work is more general and common to both sexes.

Professor Cullen's account of the novitiate at the Johns Hopkins University of those aspiring to specialize in gynaecology is of particular interest, for the time spent there and in the medical schools of this country is much the same, so that the problem is narrowed down to the question of how it can be used to the best advantage. Our method is not so standardized as it appears to be in America; our entrants are left more to follow their own bent, and, as a rule, they are not so well drilled in general pathology. With us the potential specialist in gynaecology, while holding appointments as house-surgeon and house-physician, and as house-officer in the gynaecological and obstetrical department of his hospital, prepares himself for the F.R.C.S., and perhaps for some other higher qualification. Later, when he becomes registrar, his work is similar to that of the assistants in Professor Cullen's clinic, except that at first obstetrics forms a larger part of his clinical service. The present tendency throughout medicine is to stress the study of normal function and the causes and early detection of its disorders. Hence the need, for all professing gynaecology, of a long apprenticeship in midwifery, including work in the post-natal clinic, which serves as a link joining together the two parts of the subject.

In conclusion, we venture to quote the observation of one whose description by Professor Cullen we wholeheartedly accept as "that master gynaecologist Howard A. Kelly," emeritus professor at Johns Hopkins University. In his preface to the last book under his name Professor Kelly writes: "Gynaecology, which once threw off the trammels of obstetrics, is now coyly courting her own mother, and here and there returning to her ancestral home under the guidance of rare men of acumen and skill in both specialties, an amalgamation still nascent." This statement is made, perhaps with prophetic vision, when looking back over his long experience at Johns Hopkins. There can be no doubt that the system that proves the better in actual practice is the one that will survive, and it may be that each will flourish in the soil of its own country and yet not bear transplanting.

TREATMENT OF SCOLIOSIS.

THE treatment of scoliosis, or twisted spine, presents difficult problems which are as old as orthopaedics or older, and which, when the deformity is far advanced, continue to baffle attempts at correction. The reasons for this difficulty are not far to seek. The parts of the skeleton concerned constitute the mainstay of the body in all vertebrate animals, and have especially important and onerous functions in those members of the phylum who in the course of time have assumed the erect posture. The large number of elements of which the backbone is made up, the complexity of the movements of which it is capable, its dependence for its support on the action of many muscles, and lastly, the intimate association of the column with the spinal cord and the apparatus of respiration—all these factors combine to make the problem of correction of deformities of the spine extremely difficult. As if to pile Pelion upon the Ossa of obstacles, we are furthermore confronted by the discouraging fact that it is practically impossible to get any hold of the vertebral column, except indirectly through other structures, of which perhaps the ribs are the most important and unfortunately also the most untrustworthy owing to their yielding nature and the remoteness of the points exposed to corrective pressure from those points upon which it is desired to produce effects. The variety of the causes of scoliosis further complicates the subject, especially as some of those causes are obscure, and theories advanced in explanation are not universally accepted.

Andry, the inventor of the word "orthopaedia" and author of the first book on orthopaedics, had not much to say that was helpful in treatment, but long before his time the deformity was recognized and treated vigorously by surgeons such as Ambroise Paré, and mechanicians such as Skatt (or Schacht) of Utrecht, on principles which were little altered, even after Sayre's gypsum replaced steel, till Abbott made known the principle of fashioning "windows" in jackets so as to allow and encourage expansion of the flattened ribs. When recognized and treated early and thoroughly, scoliosis, if not caused by congenital defect of bone or muscular palsy, is curable by various methods or by a combination of methods, but when the vertebrae have become grossly deformed, most authorities will admit that only palliation can be looked forward to. It was claimed for Abbott's method that the lateral flexion and rotation of the spine and the distortion of the ribs could by it be as easily over-corrected and cured as a knock-knee, but careful investigation of the clinical evidence by a committee of the American Orthopaedic Association resulted in disappointment. Many of those who have written of the treatment of scoliosis have realized that pressure on the prominent ribs of the convexity, while it may tend to correct the rotation of the vertebrae, must also tend, since the ribs are compressible, to increase their deformity, and also that, since there are almost invariably at least two curves, measures intended to correct deformity in one region are likely to increase it in another.

Elsewhere in this issue (p. 939) we publish the paper on the treatment of scoliosis by Mr. McCrae Aitken with which he opened the discussion on this subject at the Annual Meeting of the British Medical Association at Manchester, and in which he endeavoured to establish principles for the treatment of this deformity based on sound and established rules of anatomy and physiology. On no other basis can we hope to build successfully. When we examine a patient with advanced scoliosis, or Nicoladoni's well-known representation of a scoliotic vertebro-costal segment (which has been copied, with or without acknowledgement, by many later writers), we are puzzled to define the position of the antero-posterior middle line from which deviations and distortions may be measured. If we draw this imaginary line, as seems clinically desirable, through the tip of a spinous process and the middle of the sternum on the same rib-plane, and measure from that line, we shall form certain estimates of the kind and amount of distortion. If, however, say, on Nicoladoni's illustration, we take the antero-posterior axis of the vertebra for basis, an entirely different estimate will be formed of the changes that have occurred. Relativity rules in the morbid anatomy of scoliosis, and in relation to each other the vertebrae on the one hand, and the ribs and sternum on the other, are rotated in opposite directions, and the only approximately fixed base line is one drawn from the tip of the first sacral spinous process, through the pelvis, to the symphysis pubis. But as every vertebral segment in the spine may be involved, the task of describing and analysing the changes which have taken place in each one, and in its relations to its neighbours and to the selected base-line, is a very hard and heavy one.

Most present-day authorities are agreed that the outstanding element of the deformity is not so much lateral flexion as rotation, which is a normal function of the cervical and lumbar regions, whether accompanied by flexion or not. It is, however, extremely difficult to demonstrate any measurable amount of rotation in any movements of the normal thoracic region except in one or two vertebrae adjacent to the cervical and lumbar regions. Yet the worst and most resistant and obstinate deformity in advanced cases is due to rotation of the thoracic part of the column. If rotation, as R. W. Lovett maintained, is a concomitant of passive lateral flexion of the normal spine, we think it must be admitted that it only takes place to a small extent. Mr. McCrae Aitken said he had found that what he had thought was an original idea had already been expressed by W. Adams in 1854, but we think he is entitled to whatever credit attaches to the introduction of the term "unilateral lordosis"—a term, however, which seems to imply a movement which is incompatible with our ideas of the nature of a rigid body such as a vertebra, one lateral half of which could hardly move forward without the other. But W. Adams demonstrated, in the case of the celebrated Egyptologist and geologist Dr. *Gideon Mantell*, that, setting aside changes in the form of the apophyses, extensive rotation of the lumbar vertebrae could and did occur without any deviation of the spinous processes of the vertebrae concerned from the middle line of the trunk. In other words, rotation took place in this case around an axis passing through the tips of the spinous processes, instead of, as usual, round one situated more posteriorly. Mantell's case has puzzled some distinguished surgeons, but was first correctly diagnosed by Adams, whose diagnosis was confirmed at necropsy. The original specimen is, we believe, in the museum of St. Thomas's Hospital, and casts of it are to be found in various other museums.

Of late years the theory that scoliosis is the effect of ill-balanced muscular action has been revived and strengthened by recent investigations into postural tone of muscles. The fact that anterior poliomyelitis, when it affects the muscles of only one side of the trunk, is generally followed by scoliosis, together with the obviously favourable anatomical arrangement of

the spinal muscles for the production of rotation, lends support to the muscular theory of causation, which was advanced many years ago. What is new is that the effect of postural tone is now called into the pathologist's service. The speakers who followed Mr. Aitken at Manchester did not altogether accept his conclusions, but, as in many such discussions, it was not certain that those speakers were all referring to the same stage of the deformity. A method of treatment which may be efficacious in the earliest "postural" stage may be quite unfit to cope with more advanced deformities. Whether it be the ribs which rotate the vertebrae, or the vertebrae which displace and distort the ribs, may turn out to be a question of small moment when we learn the true nature and mode of action of all the forces acting on both.

HYDATID DISEASE AND PUBLIC HEALTH.

Since the war much valuable work has been published on hydatid disease in Australia and New Zealand, the parts of the British Empire where hydatids are prevalent. We have now before us No. 6 of the *Proceedings of the University of Otago Medical School*,[1] the second part of which contains three interesting papers on hydatid disease. It is edited by Professor Carmalt-Jones, who has himself recently contributed an article on the clinical aspects of the subject to our columns.[2] Dew's book, lately reviewed in this *Journal*[3] is likely to become a classic on this parasitic disease. Although hydatids are relatively rare in Great Britain, we may yet learn much that is of interest from those who have dealt with many cases—the Sauls and Davids of the profession. In New Zealand it is estimated that 100 to 150 new cases of hydatid disease in man occur each year, while the proportion of hydatid to other diseases in the hospital population is estimated as about 1 to 600. In some parts of New Zealand (Canterbury) and in Victoria the proportion is even larger, being more than 1 to 300. The life-cycle of the parasite and the mode of infestation are known. Ova from the *Taenia echinococcus* developing in the intestine of the dog are passed in the faeces and contaminate water and grass. They thus gain entry to the alimentary tract of the herbivora, and, passing to liver and lungs, form the intermediate or cystic stage. Reinfection of the dog takes place by eating these infected viscera at the slaughterhouses. Observations by the officials of the New Zealand Department of Agriculture showed that 43 per cent. of sheep and 46 per cent. of cattle harboured hydatid in lungs or liver. Similar figures are recorded concerning stock animals in the south-eastern States of Australia and in the Argentine Republic. It should be emphasized that infestation of the viscera has no deleterious effect on the flesh for food purposes—a fact of importance, since the export of frozen meat is a staple article of trade of the sheep and cattle industry of these countries. Infection of man, often during childhood, takes place from fondling and playing with dogs whose mouths and coats are soiled with ova. The mortality of hydatid disease is estimated to be between 15 and 20 per cent. The fact, therefore, that in the countries where hydatid disease is endemic its prevalence is not diminishing, but rather (especially in South America) increasing, is seriously exercising the minds of public health authorities and of those who have the welfare of the community at heart. Sir Louis E. Barnett of Dunedin, New Zealand, who was president of the 1927 Australasian Medical Congress, after giving a clear statement of the situation, describes in detail the measures that should be adopted to deal with it. He urges that a whole-hearted effort should be made to bring before the public the dangers of hydatid disease, and the facts about the mode of infection and the means of prevention. An intensive propaganda could be effected by means of public health lectures, posters, and cinematograph pictures which will appeal to both young and old. The measures to be adopted should include (1) the prevention of access of dogs to raw offal; (2) the administration to dogs of effective anthelmintics, such as male fern, areca nut, or its active principle arecoline; (3) instruction in hygiene, to prevent the swallowing of hydatid ova; and (4) the destruction of unregistered and vagrant dogs. The social sense of the community must be stirred. The active co-operation of the people with the public health authorities is required in order to prevent the spread of this menacing disease.

"AN OXFORD MOVEMENT."

"An Oxford movement" as the announced title of the Lloyd Roberts Lecture delivered at the Royal College of Physicians on November 14th by the Right Hon. H. A. L. Fisher, F.R.S., left a good deal to conjecture. One wondered whether the theme of the Warden of New College was to be the Tractarian or Puseyite movement, which generally goes by the name of the Oxford movement, or the Methodist movement, which had its origin at Oxford, or, earlier still, the Lollard movement, which was also largely inspired from that University. Mr. Fisher soon made it plain that his reference was to a secular, not a religious, movement. In the middle decade of the seventeenth century Oxford was the centre of those active philosophical discussions and investigations which later fructified in the establishment of the Royal Society. John Wilkins, afterwards Bishop of Chester, became Warden of Wadham in 1648, whereupon the group of philosophers who had been accustomed to weekly meetings in London migrated to Oxford and resumed their discussions under more peaceful conditions in the warden's lodging, and other very distinguished members of the group were drawn from Oxford itself. It would be doing Oxford too much honour, said Mr. Fisher, to trace this brilliant and sudden flare of scientific curiosity to any fundamental revolution in the academic curriculum, or any enduring triumph of the rational spirit in the University. Oxford, which was the nursery of the Royal Society, not very long afterwards burnt Hobbes's *Leviathan* and acquiesced in the expulsion of John Locke from his studentship at Christ Church. The transference to Oxford was due to political accident and the turmoil of the civil war, and it was London which had historical priority, for the weekly meetings of the "invisible college" were first held in the rooms, off Cheapside, of Dr. Jonathan Goddard, Gresham professor of physick. Mr. Fisher described some of the men who took part in this Oxford movement. Wilkins was not prolific as a writer, but had an extraordinary gift for stimulating others by the glow of his active and comprehensive curiosity, attaching to himself men who were doing important work in any line of scientific inquiry. It was a letter from Wilkins which brought to Oxford Robert Boyle, the father of English chemistry. Another distinguished member of the group was William Petty, in turn a cabin-boy, sailor, doctor, and statistician, who, being vice-principal of Brasenose, attracted attention by bringing back to life one Ann Green, who had been hanged for the murder of her child, and whose body had been handed over to the doctors for dissection. Petty was only accidentally a physician; he was really a political economist and the first to bring to political problems the science of measurement. In this brilliant company which met at Wadham, where even the manciple was a skilled maker of mathematical instruments, was Christopher Wren, who came as a commoner in 1646. Had he not become the greatest architect of his age, said Mr. Fisher, this man of various

mind would have been among its greatest mathematicians or anatomists. He helped to make improvements in the telescope, interested himself in projects for the measurement of meteorological phenomena, and also made experiments on transfusion of blood. More and more he was drawn to architecture by his native taste, his geometrical sense, and the strict discipline he had had in anatomy under the direction of Wilkins and others. During this same decade John Evelyn, a perfect specimen of the cultivated English amateur, came into association with the group, and his letters and diary bore many traces of this far-reaching movement. Incidentally Evelyn wrote a treatise on the abatement of London smoke. The Oxford group was further reinforced by a servitor from Christ Church, who was destined to make himself illustrious as a man of science. This was Robert Hooke, a man of genius, handicapped by ill health and an unfortunate knack of multiplying the jars of existence. While Wren designed St. Paul's, Hooke was the architect of the Royal College of Physicians in Warwick Lane, also of Bethlem Hospital and of Montague House, now the British Museum. He shared with Wren the intoxication of universal curiosity. He popularized the microscope, discovered the cellular structure of plants, and defined, before Newton, the doctrine of gravitation, though he lacked the mathematical ability to demonstrate it. Mr. Fisher then addressed himself to the reasons for the failure of this Oxford movement to perpetuate itself. It had its enemies in the thoroughgoing supporters of the old discipline, but Oxford was Royalist, and Charles II was notoriously favourable to the Royal Society. Nevertheless, the atmosphere from the Restoration onwards seemed in many ways subtly unfavourable to a great extension of the scientific domain. Men of science continued to work at Oxford in the age which succeeded the Wadham group, but they found intercommunion difficult, and had no great influence on the intellectual life of the University. There was no better illustration of this than the case of John Mayow (1643-79), one of the greatest names in the history of physiology. Mayow carried out his researches at All Souls, discovering oxygen and grasping the essential facts about the formation of oxides and acids, but in such isolation that even Newton and Boyle seemed to have been unaware of the significance of his published work. It was a hundred years before the greatness of this young philosopher was rediscovered, when Thomas Beddoes told his countrymen that an Englishman living in the reign of Charles II had anticipated the great Lavoisier, and had defined the secret of respiration and the principle of body metabolism. Only by slow and painful degrees, and after many an academic battle had been fought, did science recover that position of eminence in the most ancient of English universities which had belonged to it, by political accident, at the time when Christopher Wren was in his youth, and when generous minds were turning eagerly from the sterile battle of the creeds to the new and peaceful pastures of natural knowledge.

CONTROL OF PROPRIETARY REMEDIES IN NORWAY.

Next January a new law will come into force in Norway, designed to control the advertisement and sale of proprietary drugs and contrivances such as electric belts. No vendor of a so-called specific remedy, whether it be a cure for colds or a preventive of parasites, will henceforth be allowed to keep the composition of his wares a secret. The threefold object of the law is to ensure that proprietary remedies shall be potent—namely, that they shall possess the medicinal qualities calculated to effect the desired action—that their prices shall be in reasonable proportion to the cost of production, and that an unseemly advertisement campaign shall not be conducted on their behalf. The central office charged with the execution of this law during the first year of its operation is to be attached to the University Pharmacological Institute in Oslo, and the staff of this office, later to be attached to the new Pharmacological Institute, also in Oslo, will consist of a director, three chemists, and an assistant. It is anticipated that some one thousand preparations will be submitted for examination. The advertisement and sale to the public of proprietary preparations which have not been submitted to the central office before July 1st will be prohibited. With regard to proprietary preparations which have been passed for sale, four copies of the proposed text of advertisements, circulars, and the like will have to be submitted for censorship to the central office. It is anticipated that the charges for dealing with proprietary remedies will defray the costs of this office, as 25 kroner will be charged for the notification of every preparation, and 50 kroner for registration and examination. Hitherto only Austria has officially adopted a similar measure, but although the law has been enforced for some years, a comprehensive survey of its results has not yet been published. In certain other countries there have been sporadic attempts to control the sale of quack remedies; in Sweden, for example, there has existed for some time an unofficial station or office for testing proprietary preparations, and a similar office is shortly to be opened in Denmark. It is hoped that an active entente between the organizations concerned in Norway, Sweden, and Denmark will do much to render the Scandinavian countries an unproductive territory for the quacks who have hitherto exploited their credulous compatriots.

NATIONAL HEALTH INSURANCE ADMINISTRATION.

It is worth while from time to time to note the opinions of the layman experienced in administration of the national health insurance scheme, and to see how far these opinions agree with those which have been officially expressed on behalf of the medical profession. The statements of those chairmen of Insurance Committees who are not themselves either doctors or the officials of approved societies may be of considerable value, especially on the subject of medical benefit and its extensions. An interesting address at the annual meeting of the Insurance Committee for East Ham was given by Mr. Councillor F. Webster, the outgoing chairman. After reviewing the statistics showing the growth of the system since 1921, when the borough first had an Insurance Committee separate from that of the county of Essex, and observing that "complaints made against the service have been surprisingly few," Mr. Webster states his view on four matters in which the medical profession is particularly interested. He says, first, "Any step which will settle, once and for all, the position of the insurance medical and allied services in relation to general public health administration would be welcomed, with the proviso that, so long as the cost of benefits is contributed by a particular section of the population, the administration of those benefits should be kept distinct from ordinary municipal service." Next, "We ought to have all insurance services administered by one local body. I refer to dental and ophthalmic treatments, which are now being provided in a way entirely contrary to the recommendations of the Royal Commission, which stated that it is highly desirable that the organization of services which are akin to medical benefit should be entrusted as far as possible to the bodies which are responsible for the administration of that benefit." Further, with reference to the suggestion of a national maternity service, "Perhaps with this benefit more than any other it is desirable that the administration should be free from any suggestion of charity: it is essential that the mother should regard the benefit as private treatment purely, as it is only thus that success will be attained. A great number of people who would be willing to take advantage of an insurance service would certainly not like it to be thought

that they had been attended by a public doctor." Again, "One still has hopes that the extension of medical benefit to the dependants of insured persons will be brought about, and that the treatment under the Act will be made to include specialist and consultant services. At present we are only touching the fringe of true medical treatment." Pronouncements on all these matters have been made by the British Medical Association on similar, though not quite identical, lines, and there is a general agreement that the order of the two extensions mentioned in the last quotation should be reversed. The important thing, however, is that, though we move step by step and quite slowly, and though other changes in local health administration are just now more prominently in the public mind, these matters should not be forgotten or escape serious consideration, for it cannot be long before they become once more of urgent public concern. One more point is mentioned in a sentence by Mr. Webster, and it is a little surprising that it has not yet been the subject of public comment from its medical aspect. The President of the Board of Education has announced that the age for compulsory school attendance is to be raised to 15 years as from April, 1931. It is stated that the Minister of Labour is to legislate for the lowering of the age of unemployment insurance to the same year. There can be little doubt that, though national health insurance might not at the outset be involved in these changes, the lowering of the health insurance age to coincide with that of unemployment insurance must inevitably and quickly follow. It is time that this contingency was in the minds of the medical profession.

THE ROCKEFELLER FOUNDATION.

In his pleasantly written review of the manifold activities of the Rockefeller Foundation[1] its president, Mr. George E. Vincent, remarks that three hundred years have passed since Francis Bacon, in the *New Atlantis*, said that the purpose of the research institute of the imagined paradise in a fabled island was "the knowledge of causes and secret motions of things, and the enlarging of the bounds of human empire, to the effecting of all things possible." This ideal is that of the Rockefeller Foundation, with its motto, "The well-being of mankind throughout the world"; thus, during 1928 the Foundation has aided eighteen medical schools, ranging from that of Edinburgh University to the American University of Beirut, and has pledged 43 million francs to provide modern medical facilities in Lyons, which it is hoped will lead to further developments in public health. In the Foundation's programme of medical education the Peking Medical College is unique in being the only medical centre for teaching and research to which the Foundation has contributed the entire cost of land, buildings, equipment, and maintenance; this policy appeared necessary, since there was not any university or Government agency in a position to assume responsibility when the college was established. In May, 1928, yellow fever, which had disappeared from South America, except in Northern Brazil, broke out after twenty years' absence in Rio de Janeiro, probably brought by soldiers from Northern Brazil; research into the problems concerned with this disease has continued at Bahia in Brazil, Accra, and Lagos, and the identity of the African and American yellow fevers is now almost established. A graceful tribute is paid to Hideyo Noguchi, Adrian Stokes, and W. A. Young, who lost their lives in West Africa when investigating the etiology of the disease. It is suggested that those who wish successfully to fight malaria should try to "think like a malaria mosquito," so as to anticipate and frustrate its movements. During the year the Foundation granted 800 Fellowships among forty-six countries. Many appeals must come before the Foundation, for last year 462 formal applications for help were declined as they did not fall within the scope of the Foundation's present activities.

PROFESSOR WENCKEBACH.

On June 27th, 1929 (writes a correspondent), Professor K. F. Wenckebach delivered his last lecture as occupant of the principal chair of medicine in the Vienna school, from which he has retired at the age of 65, five years before his time. His farewell remarks, full of literary charm and borne on a deep undercurrent of sober wisdom, would have struck a chord of sympathy in an English audience. In a letter which he sent to the Osler Club on the eightieth anniversary of Sir William Osler's birth, Professor Wenckebach wrote that in this last lecture of his he was quoting from one man only—his old friend Osler. In his later years, being only one among the great number of teachers at one of the largest medical schools, trying to give something of permanent value to his overburdened students, three Oslerian dicta had greatly supported him. (1) On the question what stuff should be hammered into the heads of the students, Osler said: "From my point of view there is only one intellectual infection of any permanent value to the medical student—the scientific spirit and outlook and attitude of mind which he gets, often unconsciously, from his teacher and fellows." (2) Of the difficult task of the "chief" Osler said—"Only in one way lies the redemption for the director of any institute or laboratory: he must have associates who know more about certain subjects than he does himself." (3) Discussing what qualities a clinical teacher should possess to educate future doctors, Osler spoke of James Bovell, "and in him was all that could be desired in a teacher: a clear head and a loving heart." Wenckebach thus hoped that Osler's mind might live on in youthful Continental brains as it lives in the Anglo-Saxon world. The two men first met in the summer of 1901, when Osler was "brain-dusting" in Holland. This was the beginning of a lifelong friendship. Shortly before the outbreak of the war Wenckebach was called to what was then the Imperial University of Vienna, a follower of his great countrymen van Swieten and de Haen. It was through him that Osler organized a relief campaign for the starving Austrian children in the latter days of the war. Wenckebach is now planning to record the results of his researches on the heart and circulation—the work of a lifetime—in a large book which he expects to complete in five years. He hopes in his "really old days" to find time for writing historical sketches on his subject of cardiology. In May of last year he visited London as the delegate of the Austrian Academy of Sciences at the Harvey celebration, and received the honorary Fellowship of the Royal College of Physicians—"the most distinguished honour that ever could descend upon my elderly head." Into his retirement Professor Wenckebach, who feels "as if he had become part of the English medical profession, even a little bit of a Britisher," takes the good wishes of medical men in this country.

HOSPITALS AND NURSING IN MANITOBA.

In the summer of 1928 the Health and Hospital Survey Committee of the Welfare Supervision Board of the Department of Health and Public Welfare of the Province of Manitoba deputed a nurse, Miss Mabel F. Gray, to make a report on hospitals and nurses' training schools in Manitoba. Apparently the cause of the inquiry was a request from the Manitoba Association of Registered Nurses that a study of nursing conditions in the province should be undertaken. The results of the inquiry seemed to show that the conditions were unsatisfactory. Great lack of proper accommodation was found in many hospitals

for the care of obstetric cases and for communicable diseases. The investigator was of opinion that the first function of the smaller hospitals should be to provide service for maternity patients. Yet many of these hospitals had "neither labor room nor nursery"; while the wings of two hospitals which admitted unmarried mothers reminded the inquirer far too much of a prison or detention home. In one hospital the purpose of a building designed for cases of communicable diseases had evidently been forgotten; it was being used as a storage for "junk." In several instances there was evidence of faulty construction, or the use of unsuitable buildings for hospital purposes; in all but one of the small hospitals the laboratory service was inadequate, even routine urine analysis not being carried out in some establishments; and in mental hospitals, even where the best service was being given, there was serious overcrowding of chronic cases, sometimes in ill-ventilated basements. In the schools of nursing great variation in the preparation of students was found, and also in the number of hours devoted to theoretical instruction. The report urges that definite standards of teaching in nursing should be set by the Council of the University of Manitoba; that an educational director should visit the schools; that the living conditions of the nurses should be considered by the same authority; and that a Government grant, conditional upon real educational work being carried out, should be made to schools of nursing. The investigator evidently took a very wide view of her reference, and concludes her report by advising an entire reorganization of a particular home for the feeble-minded.

ROYAL MEDICAL BENEVOLENT FUND: CHRISTMAS GIFTS.

We gladly publish in our correspondence columns this week a letter from Sir Thomas Barlow, president of the Royal Medical Benevolent Fund, in which he makes a special appeal to the profession for donations to enable the Fund to give Christmas gifts to each of its annuitants and some of the more necessitous of its grantees. His appeal, we hope, will meet with an immediate and generous response. The beneficiaries of the Fund are, as he reminds us, "deprived of those little amenities of life which the more fortunate of us enjoy," and to many of them only the generosity of the profession can ensure some extra comfort at Christmas. Last year for this purpose the Fund distributed £500; this year it will be in a position to perform "this gracious and friendly act" only if there is an adequate response to the present appeal. We therefore urge our readers to make a special point of sending a Christmas donation to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, London, W.1.

The Nobel Prize for Chemistry for 1929 has been divided between Professor Arthur Harden, D.Sc., F.R.S., head of the Biochemical Department at the Lister Institute, London, and Professor H. Von Euler of Stockholm.

We regret to announce the sudden death of Sir G. Archdall Reid, K.B.E., M.B., the well-known writer on heredity and kindred subjects. We hope to publish a memoir in an early issue.

We much regret a slip which occurred in our leading article on the Panel Conference in the *Journal* of November 2nd (p. 814), where it was said, "For the last two years the Conference has had for its chairman Dr. E. K. Le Fleming of Dorset." As all concerned know very well, Dr. Le Fleming has presided over the last five annual Conferences.

MOTORISTS, DOCTORS, AND THE PUBLIC.

Discussion at Hunterian Society.

The Hunterian Society of London, meeting at Cutlers' Hall, Warwick Lane, on November 18th, with the members of the Medico-Legal Society as its guests, had an excellent discussion on the motorist, his rights and his wrongdoings. Dr. Ernest Young was in the chair.

Earl Howe (better known as Viscount Curzon, who, the president said, had had the distinction as a motorist of contributing an unusually large sum to the revenue) opened the debate by quoting from the report of the Royal Commission on Transport the fact that 6,127 people were killed on the roads of Great Britain in 1928. He was of opinion that the Act of 1903 should not be torn up, as it had worked astonishingly well, but merely revised in the light of experience and common sense. He was not in favour of abolishing the speed limit, because this would result in throwing back the police upon prosecutions for dangerous driving and nothing else. A charge of dangerous driving depended upon considerations of a highly technical nature, which the ordinary courts would not have time to investigate. Indeed, he thought there was much to be said for traffic courts, sitting with assessors. The principal causes of accident grouped themselves under carelessness, and were preventable. The standard of driving was not what it should be. This country did not insist upon a test of driving competence. While he agreed that there could not be a compulsory examination of all drivers, he believed such a test might be organized on voluntary lines, and the possession of a certificate would in a short time become almost necessary to every motorist, because of its value as evidence should he be involved in an accident, and also possibly because of a reduction of premiums by insurance companies in favour of holders.

Mr. E. B. Turner mentioned that an important committee of the British Medical Association was about to begin the consideration of the question of tests for drivers. He agreed that there should be some form of test. Many men driving on the road were not fit to be trusted, owing to defective eyesight; others were subject to petit mal or perhaps even epilepsy. Loss of limbs was a moot question; he was himself on one occasion perfectly driven by a motorist who had lost an arm and a leg in the war. Convalescents, again taking up motoring, ought not to regard themselves at once as quite fit to begin where they had left off before their illness. As for age, it was difficult to lay down any rule. Mr. Turner mentioned that he celebrated his seventy-fifth birthday by driving from Yorkshire to London at an average of thirty-five miles an hour, and felt absolutely untired at the end of the journey. The woman driver was a delicate question. Like the little girl, when she was good she was very, very good, but when she was bad—then Heaven help the others! Many women failed because they expected when in a tight place the courtesy which old Victorians like himself gave them in the drawing room. But women were improving in road sense, and no doubt would become a race of motoring Atalantas, driving fast, well, and considerately. Motoring was an exercise, entertainment, necessity, and convenience, which ought to be undertaken circumspectly and wisely by fit persons.

Mr. Mervyn O'Gorman (motoring correspondent of the *Times*) said that there was no one traffic problem, but a cohort of traffic problems; the difficulty was not in their intricacy, but in their number. He ventured upon what he called a few rudimentary generalizations. Road safety imperatively demanded the continuous attention of every traffic unit upon the job of being a unit in traffic. Anything that distracted driver or walker added to the risk of collision. There were any number of such distractions—bad naming of thoroughfares, flaring patches, vague hand signals, jay walking, and so forth. Whatever made driving more delicate could only be tolerated on the supposition that in some way it increased the acuity of the driver's attention. The psychology and physical state of the driver was undoubtedly a factor in traffic safety. A large American firm found that 50 per cent. of all the accidents to its vehicles occurred with 20 per cent. of its

drivers, but 50 per cent. of the unavoidable accidents also occurred to the same 20 per cent. of drivers, showing that these unfortunate people not only were responsible for the avoidable accidents, but got themselves into such positions that they were confronted with the unavoidable. A psychological test to eliminate such drivers would be worth the heavy tax on the motoring community which it would entail. Other generalizations submitted by Mr. O'Gorman were that the driver's intention ought always to be shown, and that he should heed the intention of other drivers; that the plea of the pedestrian for priority as road user was in reality a plea for suicide; that safe speed was itself a goal to be sought, and was essential for transportation; and that the great desideratum was the team spirit among road users, both pedestrian and vehicular.

Dr. Percy B. Spurgin thought it should be essential for everyone who took up motoring to pass an examination for medical fitness. The engine driver had to undergo periodical medical examination, and in some ways the engine driver's job did not make as heavy a demand upon his resourcefulness and attention as the motorist's; at least he had a clear road. Every commercial motorist and every driver plying for hire should be compelled to undergo medical examination; most private owners had the common sense to be medically examined more or less frequently. He thought that also there should be a form of insurance whereby unfortunate individuals who were damaged might receive compensation or assistance wherewith to reimburse hospitals and doctors for treatment received. Hospitals often treated half a dozen victims of accident on Saturday nights without receiving a penny. He thought there should be a speed limit; in towns a close limit, strictly adhered to; also a beginning age limit for drivers, though an end age limit must depend upon physical fitness and nothing else. Dr. Spurgin then made some observations, as a police surgeon, on the undue consumption of alcohol "which has not passed through the carburettor." Drunkenness was difficult to define, though the British Medical Association Committee reached as near the truth as any when it said, in effect, that a man was drunk when he was unable to perform his ordinary functions normally. There were seven stages of alcoholism—relaxation, bonhomie, expansiveness and loquacity, argumentativeness and cantankerousness, aggressiveness and pugnacity, somnolence, and finally coma, and it was a moot point at which stage drunkenness began. It was not the comatose individual who was the problem at all; it was the borderline case. Nor could it be said what consumption of alcohol was likely to make a man drunk; it was a question of the individual. But what the public had not realized was that while a man might make an elliptical walk home without attracting attention from the law, that same man in charge of a car was a public danger and ought to be arrested.

Mr. H. Massac Buist (introduced by the President as one whose able and helpful articles on motoring had interested the readers of the *British Medical Journal* for the last quarter of a century) said he hoped that presently all matters concerning motoring might be brought under one single law, clearly defined and up to date, though the diversity of administration would still remain whatever the law, and, as it did at present, would seriously impair the value of all statistics. Until within the last two years he had had the delightful duty of making whole-day or longer trials of over fifty new types of car every year, and this had left him with the conviction that cars were amazingly different from one another as to what they would do on a given road. The cars he tried each year were naturally the latest examples of engineering design, whereas the cars he met on the road were often of a design twenty years old. A good many of the drivers of such cars would insist upon doing exactly the same things as the driver of the latest car was doing. In Paris he found more consistent driving than in this country; it was difficult to know why this should be so, for many of the cars were of shaky build, but possibly the Latin temperament was quicker in its reactions. Motoring could not be confined to those who had road sense, simply because the motor had become an essential of latter-day life, but it had to be admitted that many persons on the road could only be called fair-weather drivers, and the ratio who could deal with skidding conditions was never so low as at present. Driving tests were in force in France, but the weakness of them was that they were static tests, and could not indicate the resourcefulness of the driver in an emergency. He was of opinion that there should be driving tests, but that no undue importance should be attached to the degree of skill thereby manifested. As for physical fitness, he had yet to learn of a practical scheme for forming a judgement. But the present state of affairs had some extraordinary results. A blind man was sent, as an experiment, to get a licence, and duly obtained it! One motorist of his acquaintance, still driving, had been deaf since the age of 7, and in his case at least the lack of one faculty had not apparently resulted in the sharpening of others. In conclusion, Mr. Buist said a word about doctors in accident cases. It was not at all unusual for kind-hearted local doctors, besides giving their time, to supply to the victim of an accident certain materials for which they had to pay cash, and often the first thought of the victim, having had his wounds dressed, was to jump in and ride away. He would like to see heavy fines for that behaviour, which was as mean as defrauding a tradesman.

Lord Riddell (president of the Medico-Legal Society) said that he felt acutely the position with regard to hospitals. There should be a law that all motorists who were succoured by a hospital or a medical man should thereby incur a liability for an amount recoverable by action at law, and in the meantime secured on the motor vehicle. Dr. Bernard O'Connor claimed that age had very little to do with accidents. He also pointed to the example of the London General Omnibus Company's drivers, who were the best in the kingdom. If motorists in general were subjected to the same training and examination as these drivers there would be few accidents. Dr. Campbell McClure, in proposing a vote of thanks to the speakers, said that the sooner there was a test for motor drivers the better. He had known a taxicab driver in London who suffered from progressive muscular atrophy; another who was blind in one eye and almost completely deaf; and he had seen a man with two artificial feet driving a car.

AUSTRALASIAN MEDICAL CONGRESS.

THIRD SESSION, SYDNEY, 1929.

(Concluded from page 923.)

In last week's issue there appeared some account of the opening of the Australasian Medical Congress (British Medical Association), in Sydney, on September 2nd. Reference was also made to some of the papers read in the Sections of Medicine and Surgery. Reports of the proceedings of the Congress have appeared in subsequent issues of the *Medical Journal of Australia*, from which have been derived the brief notes that alone are possible here.

Abnormal Cardiac Rhythms.

Good discussions followed introductory papers relating to pathological conditions of the cardiac action. Dr. M. D. Silberberg (Melbourne) reported a study of seventy-six cases of simple paroxysmal tachycardia, and twenty-eight cases of paroxysmal fibrillation met with in private practice. He gave a clear statement of the etiology, symptomatology, and treatment of these conditions, calling attention to the fact that in an appreciable proportion of such patients there were no demonstrable lesions or obvious causes. He recommended quinidine as the most dependable drug, its special virtue being that it prolonged the refractory period in the auricle; this implied the blocking of the advancing wave, with the result that the attack was terminated and the normal rhythm restored. He admitted, however, that this drug was neither infallible nor harmless. Dr. O. A. Diethelm (Sydney) reported a case of paroxysmal tachycardia associated with acute inflammation of the gall-bladder, and emphasized the relation between foci of infection and tachycardia. He had been disappointed in the use of quinidine, digitalis, and sedatives. Dr. N. W. Markwell (Brisbane), on the other hand, had found quinidine efficacious, provided that the heart muscle was healthy. He had given large doses at long intervals without anxiety. Both he and Dr. Joseph Coen (Sydney) agreed that cardiac arrhythmias were

not dangerous, and the latter speaker explained this on the ground that they were associated with very slight pathological changes. Mere disturbance of the cardiac rhythm was relatively unimportant as compared with the condition of the myocardium. Dr. Coen had found quinidine of very little value. Dr. S. V. Sewell (Sydney) called attention to the alarming condition which resulted when a patient suffered for long periods of time with continuously rapid heart action. He commented on the slight importance of auricular fibrillation occurring in the course of chronic affections, and reported a case in which prolonged treatment with digitalis had been very effective. Professor Carmalt-Jones (Dunedin) discussed the prognostic importance of paroxysmal tachycardia, and remarked that the auricular fibrillation was not always permanent. Dr. Silberberg, replying, agreed that gall-bladder disease was a potent source of toxic absorption; he was not sure whether the effect so produced was reflex or direct. Quinidine should be pushed if necessary, but its toxicity should be borne in mind, and advanced degeneration of cardiac muscle was a definite contraindication to its use. He recommended an initial dose of 0.18 gram every hour; this was increased to 0.35 or 0.5 gram until the result was obtained. As regards diagnosis, the history of onset was most important.

Dr. Alfred Webster (Perth) read a paper on cardiac arrhythmias, in which the conclusions of Sir James Mackenzie were severely criticized. Dr. S. V. Sewell, who followed, disagreed with this criticism, and discussed Mackenzie's findings in considerable detail. Dr. Silberberg also dealt with the importance and value of cardiographic tracings.

Chronic Pulmonary Infections.

The subject of chronic pulmonary infections in relation to the upper respiratory tract was considered by a joint meeting of the Sections of Medicine, Oto-Rhino-Laryngology, Paediatrics, and Radiology and Medical Electricity. Dr. R. Graham Brown (Brisbane) stated that bronchiectasis was often associated with nasal sinus suppuration, and emphasized the importance of early diagnosis. Any nasal obstruction should, he said, be corrected and sinus suppuration checked, since, otherwise, the bronchiectasis would not be relieved. He had been disappointed in the use of the bronchoscope as a means of drainage and lavage. Dr. Graham Brown commented also on the association of sinus suppuration with pulmonary tuberculosis. Dr. J. F. Mackeddie (Melbourne), in a paper on the diagnosis and treatment of chronic lung conditions in relation to disorders of the upper air passages, referred at considerable length to the use of x rays in diagnosis, and discussed various methods of introducing lipiodol. He agreed that artificial pneumothorax was useless without phrenicotomy, and that the duration of compression for bronchiectasis was, as a rule, three times that required for tuberculosis of the lungs. A patient whose lung had been compressed owing to the presence of an abscess should not be allowed to walk until a long interval had elapsed. Dr. E. Britten Jones (Adelaide) dealt with bronchiectasis occurring in children, and Dr. K. Stuart Cross (Melbourne) discussed the radiological appearances in chronic pulmonary infections. He urged that examination of the paranasal sinuses should be performed in all chronic lung conditions.

Dr. J. Stanley Yerco (Adelaide) described the method of injecting lipiodol into children by the crico-thyroid route under general anaesthesia. He remarked that it was necessary to ascertain previously that the patient had no idiosyncrasy to iodine. Sir Richard Stawell (Melbourne) reported a case of mistaken diagnosis due to the overlooking of the possibility of double antral infection, and called attention to the frequency with which chronic infection of the tonsils was found in pulmonary tuberculosis. Dr. E. Gutteridge (Melbourne) stressed the importance of infections of the upper respiratory tract in non-tuberculous conditions of the lung, particularly in connexion with people who were supposed to have been gassed; he had found that more than 20 per cent. of men in receipt of pensions on account of gas infection were suffering from sinusitis. He commented on the value of bronchoscopy. Dr. Cotter Harvey (Sydney) showed several bronchograms, and gave the warning that physical signs might at times be absent in bronchiectasis, and the skiagram might show no abnormality; in such patients a bronchogram enabled bronchiectasis to be detected. Dr. D. Galbraith (Melbourne) dealt with catarrh of the respiratory tract in children, and expressed the view that tuberculosis was not greatly concerned in its etiology when the children were under the age of 10. He recommended that a diagnosis of chronic bronchitis should be confirmed by x-ray examination and the injection of lipiodol, but he admitted that it was sometimes very difficult to interpret thoracic skiagrams in children.

Diverticulitis.

Professor G. Gordon Bell (Dunedin), president of the Section of Surgery, gave an address on diverticulitis, with special reference to its difficult and dangerous complications. He commended Telling's classification, and detailed the etiology, symptoms, sequels, and treatment recommended, emphasizing medical measures which he claimed were very often of considerable importance. He reported five cases of this condition, stressing the special significance of each. Dr. H. R. G. Poate (Sydney) agreed that the clinical syndrome given by Professor Bell covered the ground, but he thought that the most common type was that in which left-sided abdominal pain occurred. If, with this, there was slight pyrexia and leucocytosis, a radiological examination usually revealed diverticula. As regards diagnosis, a tender mass in the right iliac fossa, with pain, slight rigidity, slight pyrexia, and leucocytosis, was almost diagnostic of diverticulitis. He agreed also that medical treatment was particularly valuable. Subsequent speakers reported various cases of diverticulitis, and discussed the leading points in diagnosis and treatment. Dr. B. T. Edye (Sydney) mentioned two forms of diverticulitis of the duodenum which he had treated.

Carcinoma of the Colon.

Dr. Victor Hurley (Melbourne) read a paper based on the analysis of 81 cases of carcinoma of the colon. Comparing his series with those of Carson (110 cases) and Burgess (259 cases), it appeared that carcinoma was roughly five times more frequent in the left half of the colon than in the right. He gave details of diagnosis and treatment. Dr. B. T. Edye emphasized the importance of persuading patients to seek treatment early, when difficulty with the bowels arose after middle age. Dr. H. B. Devine (Melbourne) drew attention to the lasting value of early surgical treatment in this condition.

Simple Adenomata.

Dr. H. R. G. Poate (Sydney) read a paper on the so-called simple adenomata, with particular reference to those of the parotid, the breast, and the thyroid gland. He said that a large proportion of malignant tumours of the parotid arose from degeneration in an old-standing adenoma, and that, therefore, simple tumours of this gland should always be removed. He condemned the practice of making an exploratory incision into a breast tumour of doubtful malignancy, and commented on the mechanical disabilities which resulted from simple growths in the thyroid gland. Dr. B. T. Zwar (Melbourne) remarked that the rapid increase in size in parotid tumours often led to an error in diagnosis, but, in any case, the tumour must be removed at all costs. Dr. L. M. McKillop (Brisbane) thought it was better to remove the whole breast when a fair-sized adenoma was present than to run the risk involved in a local incision.

Progress in Obstetrical Practice.

Dr. Henry Jellett (Dunedin), president of the Section of Obstetrics and Gynaecology, discussed the future of obstetrical practice, emphasizing the value of ante-natal care and the importance during normal labour of asepsis and the absence of haste. He commented on the more intensive training of medical practitioners and midwives in Holland, and urged that the medical profession should be freed from the servitude of normal midwifery. Dame Janet Campbell remarked that the subject of maternal mortality had brought the medical practitioner and the public health officer into close association. Largely owing to the influence of Sir Ewen Maclean, the British Medical Association had taken steps to educate the general public, and had given much assistance to the Ministry. She then gave an account of the progress of ante-natal supervision in England, and expressed the hope that, eventually, clinics would be established as consultation centres, with a specialist in charge. Improvements were being effected in the training of midwives, but the speaker disagreed with the practice in Scandinavia and Holland, which handed over complete control of the patient to the midwife. Professor J. C. Windeyer (Sydney) commented on the duration of the training of the obstetrical nurse and the medical student, which he

maintained was too short in Australia. A mothercraft department had been instituted at the Royal Hospital for Women, Sydney, and this example was being followed elsewhere. Clinical obstetrics deserved a higher place in the medical curriculum, but the speaker deprecated too early teaching of this subject. Dr. E. S. MORRIS (Sydney) uttered a warning against comparing statistics of different countries, which were not always strictly comparable. This was the case as regards those of England and Wales in comparison with those of Australia in general and of New South Wales in particular. Sir EWEN MACLEAN remarked that the circumstances in which the general practitioner had to work were often unsatisfactory; in some cases the patient's family urged instrumental intervention when it was undesirable. Enlightenment of the general public was the greatest factor to be considered in future, and the general practitioner must receive adequate remuneration for his work. He believed that by providing a scheme of insurance real benefit would accrue, but he did not suggest that such a scheme should be adopted in Australia. Sir TRUBY KING (New Zealand) spoke about cranial birth injuries, which, he thought, were far too prevalent in New Zealand.

Ante-partum and Post-partum Haemorrhage.

A good discussion of haemorrhage in connexion with labour was opened by Dr. E. BRETTINGHAM MOORE (Hobart), who described the etiology, pathology, and treatment of ante-partum haemorrhage. Evidence had been obtained implicating chronic nephritis, but it was difficult to prove how far a true toxaemia was concerned, and how much was due to a deficiency disease. The changed condition of the uterine walls was probably partly responsible, and certain anatomical factors, such as the muscular distribution in the lower uterine segment, had to be borne in mind when considering the cause of this condition. Dr. J. A. CAMERON (Ipswich) read a paper on post-partum haemorrhage, in which he discussed the incidence and causation, stressing the importance of repairing laceration, removal of the retained placenta, promotion of uterine retraction, the use of pituitary extract, and other measures. Professor J. C. WINDEYER (Sydney) thought that it was best to leave the membranes unruptured in accidental haemorrhage, except when some intrauterine manipulation had to be performed. He mentioned the value of external version before the membranes were ruptured with the bringing down of a leg, and also scalp traction by means of suitable forceps, which he had found to give good results.

Natal and Neo-natal Mortality.

The subject of natal and neo-natal mortality was discussed by a combined meeting of the Sections of Obstetrics and Gynaecology, Paediatrics, and Preventive Medicine and Tropical Hygiene, a paper prepared by Professor MARSHALL ALLAN being read by Dr. R. W. CHAMBERS. Professor Allan commented on the failure to reduce the infantile mortality under the age of one month, though there had been benefit in later periods. The problem mainly concerned the obstetrician, and only 20 per cent. of deaths in an investigation of his own had been shown to be due to syphilis. Chronic nephritis and pregnancy toxaemia were two more important factors, but the chief causes of intra-natal death were asphyxia and birth injuries. Professor Allan discussed the methods of prophylaxis and treatment which had been devised to improve the neo-natal death figures, and thought that a reduction of 40 per cent. of the present mortality rate might be reasonably expected. Dr. P. L. HIPSLEY (Sydney) followed with a paper based on the records of the Royal Hospital for Women, and indicating the seriousness to be attached to the toxaemias of pregnancy. The installation of a mothercraft department at this hospital had considerably reduced the death rate in premature infants. Cranial and intracranial damage must be borne in mind and prevented when possible. When intracranial haemorrhage was suspected lumbar puncture should be performed as soon as the signs of shock passed off; it was repeated until definite improvement became manifest. In dealing with asphyxia pallida the infant's lungs should be expanded rhythmically, with a mixture of 95 per cent. oxygen and 5 per cent. carbon dioxide. Dr. AGNES BENNETT (Wellington, New Zealand) read a paper based on the clinical study of 92 stillbirths and neo-natal deaths in 2,000 deliveries. She thought insufficient emphasis had been laid upon the vulnerability of the newborn to outside infections. It was possible that the administration of vitamin E to mothers might prove to be beneficial as regards the prevention of stillbirths.

Treatment of General Paralysis.

Dr. CLIFFORD HENRY (Sydney) read a paper embodying the results of treatment by malaria of patients with general paralysis of the insane. After giving an account of the statistics concerned, he remarked that this treatment was contraindicated in patients with advanced active tuberculosis, or with severe renal disease. There appeared to be some parallel—though a doubtful one—between the mental and physical improvement of the serological condition. Dr. R. S. ELLERY (Melbourne) thought it was not justifiable to use fever therapy as a routine in most psychoses. It was of no value in dementia praecox, but when epilepsy of syphilitic origin was present malaria treatment might be of considerable benefit. Various reports were given of the use of malaria therapy in Claremont, Brisbane, and Parkside, and Dr. Ellery exhibited a film illustrating this treatment, in which remarkable improvement in the patients was graphically demonstrated by photographs. Dr. E. T. HILLIARD (Orange) read a paper on tryparsamide in the treatment of general paralysis, and stated that 60 per cent. of the patients had been undoubtedly benefited. Improvement was particularly manifest in the excited, expansive, and psychotic type; the dull paralytic was less favourably influenced. A brisk discussion followed.

Trauma and Functional Neurosis.

The Sections of Neurology and Psychiatry, Surgery, and Orthopaedics combined for a general discussion of trauma in relation to functional nervous disorders, which was opened by Sir HENRY NEWLAND (Adelaide). Dr. H. SKIPTON STACY (Sydney) read a paper on the surgeon's point of view, in which he warned against the danger of diagnosing a functional disorder when an actual organic lesion was present. Dr. H. F. MAUDSLEY (Melbourne) commented on the frequency of functional disorders in accidental injuries sustained in industrial occupations, and discussed the etiology carefully, urging medical practitioners to acquire a wider knowledge of psychological medicine. Professor J. P. LOWSON (Brisbane) reported a case of functional disorder following a blow to the head, thus bringing for the first time into the open the consequences of a previous undetected mental instability. Subsequent speakers continued the valuable and practical discussion, emphasis being laid on the value of different forms of organic treatment.

Bone Dystrophies.

Dr. H. R. SEAR (Sydney) read a paper on the bone dystrophies before a combined meeting of the Sections of Paediatrics, Orthopaedics, and Radiology and Medical Electricity. He dealt solely with those bone dystrophies which came under the heading of congenital developmental errors, and stated that the lesions fell naturally into two main groups of diseases—those especially affecting the membranous bones, and those affecting the long bones. He enumerated the various dystrophies in the skull and limbs in detail, and described the deformities produced. He was followed by Dr. H. M. HEWLETT (Adelaide), who showed skiagrams of diaphyseal achalasia and unilateral Ollier's disease.

Pulmonary Disease among Miners.

Dr. KEITH MOORE (Canberra) read a paper on pulmonary disease in the mining industry in Western Australia, Tasmania, and Victoria, giving statistical results and indicating how the Government was co-operating in the investigation and treatment of this condition. He discussed Watkins-Pitchford's theory of latent silicosis, which he thought offered an explanation of the apparently abnormal percentage of complicated silicosis found on re-examination of presumably normal persons. Dr. R. C. E. ATKINSON (Perth) remarked that one difficulty encountered was the finding of suitable occupation for men who had been thrown out of employment and had to be placed on full pensions. In the subsequent discussion reference was made to the paper by Dr. Charles Badham in the report of the Director-General of Public Health of New South Wales for the year 1927.

Miscellaneous Topics.

In the Section of Pathology and Bacteriology, Professor PETER MACCALLUM (Melbourne), president of the Section, gave a useful and critical address on the confused terminology of haematology, with special reference to the blood changes in anaemia. Dr. JEAN MACNAMARA (Melbourne) reported the successful treatment of acute poliomyelitis by human immune

scrum. In association with Dr. F. M. Burnet, Dr. Macnamara also contributed a paper relating to the activity of stored anti-poliomyelitis serum in experimental poliomyelitis. Dr. C. H. Kellaway (Melbourne) read a paper on immunization to snake venoms, and Dr. C. W. Adey (Melbourne) commented on the antigenic value of anatoxin. Professor J. Burton Cleland (Adelaide) discussed the pathology of endometriomata, which gave rise to considerable discussion. Dr. A. V. Meehan (Brisbane), president of the Section of Orthopaedics, summarized the operative procedures for stabilization of the foot. He indicated the various types of deformity, and suggested a suitable treatment in each case.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

ANNUAL DINNER IN LONDON.

The annual dinner of the Society of Medical Officers of Health was held at the Piccadilly Hotel on November 14th, with Dr. J. J. Buchan of Bradford, president of the society, in the chair. Among the principal guests were Sir Arthur Robinson, First Secretary to the Ministry of Health; the Bishop of Sodor and Man; Surgeon Vice-Admiral A. Gaskell; Lieut.-General H. B. Fawcus; Sir John Rose Bradford, P.R.C.P.; and Dr. H. B. Brackenbury.

Sir Arthur Robinson, proposing the toast of the society, regretted the absence of the Minister of Health, who was detained in the House of Commons. He suggested that the society, having been founded in 1856, had now reached the years of discretion. Its success was manifest in that its membership was about 2,000, its branches had spread to various countries abroad, and it produced valuable literature. Possibly even more beneficent were the discussions organized locally, which were most useful for enabling a sound judgement to be reached on points in which the Ministry and the society were united in a valued and valuable partnership. In the development of the services of public health the leading position occupied by this country was admitted by the Rockefeller Institute when it founded the London School of Hygiene, but the time to rest had not yet come, as was shown by the present problem of refuse disposal in London—a difficulty complicated by several local authorities being concerned. A joint committee had been appointed to investigate the question, but Sir John Gatti's lamented death had postponed the issue of a report. Moreover, as regards food, much remained to be done in carrying the information derived from research into practical effect in the country generally. Sir Arthur Robinson remarked that the coming into operation of the Local Government Act of 1929 would soon enable medical officers of health and the Ministry to operate more effectively in many ways. He recounted the history of the growth of public health legislature, and said that after a succession of minor changes the time always came for some great measure, such as the present Act, which provided a new authority to take over the administration of poor relief, conducted with such devoted ability by the guardians for a century. Such a task would necessarily be undertaken slowly and gradually. With the passing of the multiple control of health services the Ministry would be able to acquire full information about the health services in every county; it was the duty of the local authority to collect the facts, and also to devise appropriate propaganda. A new survey of the local government areas was urgently necessary, and the medical officers of health—administrators as well as clinicians—would have to determine eventually the general policy of the local authority. This provision of the Act, it was added, had been so far insufficiently recognized by medical officers of health. In addition to forwarding research, the local authority would gradually raise the standard of those institutions which under the guardians had not reached the highest levels of excellence. Sir Arthur Robinson referred briefly to the threat which some had found in the Act, that the voluntary principle in hospitals would be endangered. As a refutation of this he cited the illustration in the progress of Bradford Hospital since it had been taken over by the municipality; the new Act would indeed facilitate the provision of proper hospital accommodation for every county. Medical officers of health could learn very much from the way in which voluntary hospitals were being carried on, and they must arrange for the fullest co-operation so that adequate bed accommodation should be secured everywhere. The financial side of the Act might be regarded as a salutary exercise in mental gymnastics. In conclusion, he referred to the long-standing and fruitful alliance between the British Medical Association and the Society of Medical Officers of Health, and announced that the Minister hoped to introduce a bill at an early date to provide for the superannuation of local government officers.

The President (Dr. John Buchan) thanked Sir Arthur Robinson for the kindly way in which he had submitted the toast. A statesmanlike account had been given of the public health work of to-day, and emphasis had been laid on the necessity of co-operation between all the authorities concerned. Dr. Buchan gave the assurance that the Society of Medical Officers of Health would maintain the closest possible relationship with the Ministry in the good work which had now been initiated there. The society had already taken active measures as regards the education of the public, though the difficulties of this work were very great in some places.

Professor J. Johnstone Jervis, president of the Yorkshire branch of the society, after eulogizing the president, proposed the health of the guests, and spoke in particular of the great debt of gratitude the society admitted to Sir Robert Bolam and Dr. Brackenbury for all their help in the past. Four of the guests replied briefly. The Bishop of Sodor and Man recalled his eight years as vicar of Bradford, and touched on the co-operation which was necessary between the Church and those who were striving to make man better in health. Town-planning, though a great ideal, was surpassed by life-planning, and at the basis of the improvement of society lay the improvement of personal character. Sir John Rose Bradford suggested that his own presence on this occasion was due to recognition of the fact that maintenance and improvement of the public health was indeed part of medicine as a whole. Sir Robert Bolam expressed gratitude for the most interesting revelations made by the representative of the Ministry of Health. Those who were engaged in the service of the public health had now in front of them a greater opportunity than had occurred for several centuries. They could indeed make the work of the medical profession more fruitful in promoting the health of the community than had ever been the case before. Mr. J. H. Palin, M.P., said that it was at last realized that preventive medicine would be the salvation of the country. The present Government would undoubtedly do its utmost to help.

Alderman H. T. Pullan, J.P., chairman of the Bradford Health Committee, proposed the health of the president, and mentioned that for the second time in history a Yorkshire representative occupied this position. He paid a high tribute to the work of Dr. Buchan and his colleagues in Bradford. Dr. R. A. Lyster proposed the health of the executive secretary, Mr. G. S. Elliston, to whose enthusiasm and painstaking labours was due the great advance made by the society. His approaching retirement was a matter for very deep regret.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The Buckston Browne Annual Dinner of Fellows and Members.

The second Buckston Browne annual dinner of Fellows and Members of the Royal College of Surgeons of England was held on Thursday, November 14th, at the College, Lincoln's Inn Fields. The President, Lord Moynihan, was in the chair, and had beside him on his right hand the Right Hon. Arthur Henderson, Secretary of State for Foreign Affairs, and on his left hand Viscount Lee of Fareham, chairman of the National Radium Commission. The company numbered in all one hundred, of whom approximately one-half were Members of the College and the remainder Fellows.

In accordance with the procedure laid down last year the toasts were limited to those of "The King" and "The Donor," and no formal speeches were made. The President, however, welcomed in a few happy words the presence of Mr. Henderson and Lord Lee, and two other laymen, Mr. Bernard Darwin and Mr. Louis Baron; also a member of our profession too seldom seen at medical gatherings, Sir Wilfred Grenfell of Labrador, and another,

Dr. John Dixon, the oldest living holder of the M.R.C.S. diploma, now aged 98. Speaking of the arrangements for holding primary examinations for the Fellowship in Canada and Australia, Lord Moynihan said that the aim of the Council to-day was to make the College the centre of surgical research throughout the Empire. He then asked all present to drink the health of the donor of the banquet, and announced that on the previous day Mr. Buckston Browne had been appointed a Hunterian Trustee. The toast was received with musical honours, and thereafter the company adjourned to the lecture theatre to see a cinematograph film of Down House, Kent, the home of Charles Darwin.

In introducing his Down House film Mr. Buckston Browne explained that he only did so because of Sir Arthur Keith's absence through illness.

"Within the last two years," he said, "Sir Arthur Keith and I have been successful in the acquisition of this property. The house has been restored as far as possible to its condition in Darwin's time. It is sixteen miles from London, and open freely to all visitors on Sundays, and weekdays except on Fridays. The ground floor is to be retained in perpetuity as one of the sacred shrines of Science. Apart from house and gardens, there are some eighteen acres of land, with good road frontage, and it is the dream of Lord Moynihan, our President, to establish upon this land laboratories for the prosecution of surgical biological research. John Hunter had his farm at Earl's Court, where he kept his animals and performed his experiments, and, incidentally, where he boiled the body of O'Brien, the Irish giant. We wish that the Down domain should be to the Royal College of Surgeons of England what the Earl's Court farm was to John Hunter. Such a scheme if realized will be unique in the glorious story of British surgery. Upon the screen you will see the front of the old house, where, as stated on the gate-post, 'Darwin thought and worked for forty years, and died 1882.' The 'Old Study' will be shown, whence issued *The Origin of Species*, the very greatest of all scientific treatises. It fell, like a bolt from Jove, upon a too-credulous world, and shook it from pole to pole. You will see the actual chair, given by Mr. Bernard Darwin, in which *The Origin* was composed, and the very knee-board on which it was written. You will see the 'Sand-walk' where Darwin walked and thought, and the 'Worm stone' *in situ* on the upper lawn, with which the investigation into the work done by earthworms was made. Darwin's bust by Woolner, and his portrait by the Hon. John Collier, will be seen, and the drawing-room, and actual piano and couch, where Darwin rested at regular intervals and listened to his wife's music. On the piano, under Collier's portrait, rests an album presented to Darwin by his German scientific friends; a gentleman is shown opening the book at the beautiful portrait of Haeckel, who did in Germany for Darwinism what one of the greatest of our M.R.C.S.'s—Huxley—did for it amongst all the English-speaking peoples. And, lastly, do not let us forget in this College of Surgeons that Darwin was the son, and the grandson, of distinguished and hard-working medical men. It was upon the proceeds of their toil that Darwin was able to live free from all pecuniary care. Had this capital not existed, it is more than likely that *The Origin of Species* would never have been written."

At their departure the guests were offered, as a memento from their host, framed reproductions in colour of the portrait, believed to be that of John Hunter by Gainsborough, which Mr. Buckston Browne presented to the College four years ago. This picture was described and discussed by Sir Arthur Keith in the *British Medical Journal* of February 11th, 1928.

Scotland.

William Mackenzie Medal.

The William Mackenzie Medal "for original work in ophthalmology of outstanding merit," which has been awarded this year to Mr. W. S. Duke-Elder, M.D., D.Sc., F.R.C.S., of London, is to be presented to him at the Glasgow Eye Infirmary, on December 2nd, at 8 p.m. Mr. Duke-Elder will then deliver an address on the clinical applications of the newer conceptions in the physiology of the eye.

Welfare of the Blind in Scotland.

The Department of Health for Scotland has issued a circular dealing with the changes which will result in the administration of the Blind Persons Acts under the Local Government (Scotland) Act, 1929. Grants for the welfare of the blind will cease to be payable after May 15th next, and these will be merged in the general Exchequer contribution distributed to local authorities. As the income of voluntary associations for the welfare of the blind is at present derived partly from voluntary sources and partly from contributions by local authorities and Government grants, the discontinuance of the direct payment of Government grants to voluntary associations will mean a loss of some £16,000 to the latter. General Exchequer contributions will only be made direct to voluntary associations in respect of national services, such as the production of literature for the blind. It is suggested, therefore, that negotiations should be entered into between voluntary associations and the local authorities concerned with regard to the contributions which should now be made by the latter to make up for the loss which would otherwise be sustained by the voluntary associations. The Department of Health has requested the Scottish Advisory Committee on the Welfare of the Blind to prepare a revised model scheme, which will be issued as early as possible for the guidance of county councils that may have to prepare new schemes owing to the extension of their areas.

Crusade Against Tuberculosis

A lecture on "Tuberculosis and the crusade against it" was delivered at Edinburgh on November 6th by Dr. Harley Williams, assistant commissioner to the National Association for the Prevention of Tuberculosis. Sir Robert Philip, vice-chairman of the association, presided. The chairman spoke of the enormous sums of money which tuberculosis cost the nations of the world. Our nation's system of combating the disease was unequalled, and some forty-two years ago there was initiated in Edinburgh the first systematized attempt to attain this end. This system had now been more or less adopted throughout the world. In the interval the mortality from tuberculosis had fallen to two-thirds, and in the last twenty years to one-half, and the decrease was steady and accelerating. The National Association for the Prevention of Tuberculosis had been founded in 1901 to carry on education of the public in regard to measures for eradicating this infection, and to create a reserve fund for helping on any important discovery in relation to the disease. Dr. Harley Williams said that owing largely to the modern way of regarding tuberculosis as a broad social problem it occupied now only third place among the great causes of death, but was still the most definite indication of the way in which the community's life fell short of the ideal of a civilized nation. In Scotland at the present day no fewer than one person out of every three between the critical ages of 15 and 25 died from tuberculosis of the lungs. He warmly commended the idea of open-air schools, and said that in one open-air school the average attendance for the last two years had been 97 per cent. of the possible, the highest in all the schools of a certain county of Scotland. A neglected point in hygiene was the care of the skin. Much might be done to harden the skin by judicious training, and the fashionable cult of sun-worship had shown to what extent a form of energy might be stored in the skin from ultra-violet rays from natural or artificial sources. The lecturer produced charts in support of the opinion of Sir Robert Philip that during the lifetime of many present-day persons tuberculosis would be reduced to negligible proportions.

Glasgow Veterinary College.

At the annual distribution of prizes at the Glasgow Veterinary College, Professor John Glaister, who presided, said that during the past year there had been a fairly good influx of new students. The college had at the present time 26 students, of whom 19 were going through the ordinary curriculum, and 7 were taking a special diploma in veterinary surgery and medicine. The college was turning out good results, despite the withdrawal of the Government grant some years ago, when it had been decided that one veterinary college was sufficient for Scotland. The chairman also mentioned that five of the

students were women, of whom one had passed the final examination, she being the first woman to take the diploma of M.R.C.V.S. In regard to the question of finance, he mentioned that if the college had forty or more students they would then be free from the need for a grant. During the past year the college had received substantial aid, amounting to £1,500, from education authorities and town and county councils in Glasgow and the West of Scotland, and the governors were still hopeful that the Government grant might be renewed.

Central Midwives Board.

The examinations of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, and Dundee, have just concluded with the following results. Out of 146 candidates who appeared for the examination, 135 passed. Of the successful candidates, 58 were trained at the Royal Maternity Hospital, Glasgow; 23 at the Royal Maternity Hospital, Edinburgh; 2 at the Maternity Hospital, Aberdeen; 6 at the Maternity Department, Royal Infirmary, Dundee; 16 at the Elsie Inglis Memorial Hospital, Abbeyhill; 7 at the County Maternity Hospital, Bellshill; 7 at Barshaw Hospital, Paisley; 5 at Stobhill General Hospital; 4 at the Govan Maternity Cottage Hospital; and the remainder at various recognized institutions.

Ireland.

Royal Medical Benevolent Fund Society of Ireland.

THE Central Medical Committee of the Royal Medical Benevolent Fund Society of Ireland records with sincere regret, in its eighty-seventh annual report, the loss during the past year through death of Sir Arthur Chance, one of its honorary secretaries. Sir Arthur succeeded the late Sir Andrew Horne on the latter's resignation through ill health in 1925. He brought to the service of the society a keen business instinct combined with a lively sympathy in its work. Ill health for some months before his death hindered his activities, but his interest in the Fund remained unabated, and he gave the utmost help he could up to the closing days of his life. At the invitation of the committee Mr. Andrew Horne has consented to take Sir Arthur Chance's place, and is welcome, not only on personal grounds, but also because he bears the honoured name of his father, who was so closely associated with the work of the society in days gone by. The committee also records the loss of Dr. Louis Cassidy, master of the Coombe Hospital, under tragic circumstances in the hunting field, and of several other sympathetic supporters. It tenders its thanks to those branch secretaries who continue to work actively in the service of the society, too often meeting with disappointing results. Reports from several branches exemplify the need of personal canvass to elicit aid from doctors who have not already acquired the habit of subscribing to the Fund. The meagre response to repeated efforts of active secretaries shows how difficult it is to collect money by the method of circularization and letter writing. The British Medical Association has offered to help the society in bringing the claims of the Fund before the members of the Association, and it is hoped that by collaboration between the society and the Association a scheme may be evolved which will help the central organization and the branches in the work of collection. Suggestions as to the formation of such a scheme would be welcomed by the Central Committee. The number of grants awarded during the year was 83, as compared with 90 in 1927–28, and 81 in 1926–27. The amount disbursed in grants was £1,863, as compared with £2,071 and £1,762 in the two previous years. The average amount of the grants was £22 6s. 6d., as compared with £23 0s. 3d. recorded in the last report. The recipients included five medical men, nine orphans, and sixty-nine widows: the Society of St. Vincent de Paul and the almoner of the Adelaide Hospital aided and supervised some of those benefiting from the Fund. The outstanding feature of the balance sheets now presented is the large amount received during the year from bequests. At the last annual meeting it was reported that under the will of the late Mrs. Hepburn, widow of the late Mr. W. J. Hepburn, surgeon to the Meath Hospital, the Fund would benefit to a considerable degree; Mrs. Hepburn died in May, 1928, and by her will, of which Sir William Taylor is sole executor, she bequeathed to the society the sum of £500 in memory of her husband, and half the residue of her estate. The legacy of £500 was paid to the society in November last, and in February it received £2,846 on account of its share of the residue—a total of £3,346. Mrs. Hepburn was a generous subscriber to the Fund while she lived, and this noble benefaction is a worthy memorial of her husband, who was one of the members of the first Central Committee named in the deed of trust approved at the general meeting on June 6th, 1892. The committee also received a bequest of £100 from the late Miss Anne Kavanagh, and the total receipts from bequests during the year amounted to £3,446. Dividends and interest show an increase of about £21, but no life membership donations were received during the year. The President of the Royal College of Physicians of Ireland, Dr. W. A. Winter, a life member, gave a generous donation; sums paid through the central treasurer amounted to £196, and those received through branch treasurers amounted to £456. The committee received a grant of £10 from the Irish Medical Association, and expresses gratitude to the British Medical Association for remitting £10 subscriptions collected, and for £26 from the Medical Insurance Agency. The South-Eastern Branch of the British Medical Association also contributed. Although there are reasons for pleasure at the increased financial strength of the society, it is pointed out that by far the largest source of income is that arising from dividends and interest; the contributions of the living members of the profession are quite inadequate to maintain its work. The committee expresses its deep gratitude to those members of the medical profession who subscribe year by year, but it deplores the apathy of the great majority who do nothing to aid this Fund, which is the only one in Ireland specially concerned with the welfare of needy doctors and with the widows and orphans of their professional brethren.

The Mater Misericordiae Hospital.

The report for the year 1928 of the Mater Misericordiae Hospital in Dublin, familiarly known as the "Mater," is presented by the Sisters of Mercy, who have the hospital under their care. The number of beds available has been increased gradually from the fifty when the institution was founded in 1861 to 412; and the number of patients admitted last year was 4,686. Extension of the laboratory to meet the requirements of modern diagnosis has been effected; and the x-ray department is now under reconstruction. A private nursing home for ninety-eight patients is attached to the hospital; and it is interesting to learn that a considerable portion of the income required to run the public hospital is derived from the fees received in the home. The report on the year's work is adorned with photographs of the hospital and of a group of members of the visiting medical staff. An alphabetical list of the former pupils of the Mater Misericordiae Hospital at present in practice in many parts of the world is appended to the report.

The Belfast Hospitals' Pharmacopoeia.

The North Irish Pharmacists' Association of Belfast has issued an official pharmacopoeia of hospitals in Belfast in a convenient form for the pocket. In this pharmacopoeia are printed general formulae, with children's, gynaecological, ear, nose, and throat, eye, and skin prescriptions. Each prescription is set out clearly for ready reference, and an unusual but valuable feature of the pharmacopoeia is a price list at the end, which has been prepared as a guide with regard to the cost of each prescription to hospital patients. In a foreword to the booklet it is stated that the prices quoted apply only to hospital patients, and that in cases of obvious hospital abuse chemists are at liberty to exact the ordinary charges. If hospital authorities are notified of such cases of abuse the information will enable them to take any necessary action. The price of the pharmacopoeia is 2s. net, and copies may be obtained from any of the Belfast hospitals.

England and Wales.

The Central Public Health Committee for London.

THE names of the persons proposed for the Central Public Health Committee of the London County Council were submitted at the meeting of the council on November 19th. The committee is to consist of twenty-six persons, of whom eighteen will be members of the council, and eight co-opted. The members of the council who have been selected include two medical members, both women—namely, Dr. Stella Churchill and Dr. Barrie Lambert. The eight co-opted members include two medical men—namely, Mr. H. L. Eason and Mr. Somerville Hastings. This early appointment has been made in order that the committee may give preliminary consideration to the very important duties in relation to hospitals and medical services which devolve upon it. It is not possible, however, for the co-opted members to act on ordinary public health matters until April 1st next, and therefore the existing Public Health Committee, which will ultimately be merged into the new body, will be kept alive until that date in order to deal with such matters. The Public Assistance Committee, with thirty-two members of the council and sixteen co-opted members, has also been constituted, and among the co-opted members of this committee, as well as of the Central Public Health Committee, are a number who have served on the Metropolitan Asylums Board. The Minister of Health, afte[illegible]sentations made by various bodies [illegible]cil's administrative scheme under th[illegible] Act, has approved the scheme subject to certain minor modifications which involve no question of principle. The Central Public Health Committee will, in due course, take the instruction of the council as regards the arrangements for the appointment of its subcommittees, which may consist either wholly or partly of members of the committee. It is pointed out that a number of persons will be required for manning the subcommittees, which will deal with hospital visiting and hospital area administration, as well as for manning the local committees and district subcommittees of the Public Assistance Committee, which will deal with relief. Many names have already been submitted, but the council will welcome the opportunity of considering the names of additional persons with the requisite experience as members of public authorities or voluntary associations who are in a position to devote the necessary time to the new duties.

Cost of Tuberculosis Treatment.

A memorandum (122C/T) has been issued by the Ministry of Health showing, as in previous years, in tabular form under various headings, the weekly cost of treating patients with tuberculosis at various residential institutions in England and Wales during the year ending March 31st, 1929. The corresponding figures for the previous two years have been inserted, when available, and it appears that in more than one-half of the institutions there has been an increase in the weekly cost of each patient. Although in some instances this increase is attributable, either wholly or in part, to additional expenditure on renewals or repairs, in many institutions the rise appears to be due to the fact that a smaller number of beds are occupied. A warning to local authorities is therefore repeated that everything possible should be done to keep the beds in such institutions filled by obtaining patients from the authorities of other areas who are in need of such accommodation.

Barrasford Sanatorium.

Dr. Cecil G. R. Goodwin, medical superintendent of the Barrasford Sanatorium, Northumberland, in his annual report for the year 1928, suggests that it would be an advantage if the term "the open-air treatment of tuberculosis" could be abolished, as its continued use is misleading to the public. At Barrasford Sanatorium the results of treatment in 1928, when the weather conditions were favourable, were almost identical with those of the previous year, when these conditions were very bad. Fresh air—meaning by that superventilation—in his opinion, is the least valuable of all the factors that go to make up sanatorium treatment. At Barrasford normal ventilation of rooms is maintained, but drastic exposure of patients to the weather has been eliminated as far as possible. Of first importance to the tuberculous subject is rest; and by means of this therapeutic measure, with other methods of treatment—for example, by artificial pneumothorax or sanocrysin injections as auxiliaries—the immediate results have been very good. Healing, even under the most favourable conditions, takes a considerable time, and it is never attained in the comparatively short period that patients are able to stay in a sanatorium; nevertheless, Dr. Goodwin believes that the tuberculosis problem is gradually resolving, and the average type of tuberculous case met with nowadays is less serious than the average type in the past. At Barrasford Sanatorium fewer pulmonary haemorrhages occur during treatment, and a history of this symptom is not so frequently elicited as it was ten years ago. Moreover, a larger proportion of patients coming to the sanatorium for the first time show on admission clear evidence of fibrosis; in other words, of natural resistance to tuberculous infection. The opinion is strongly held at Barrasford that the type of disease prevalent in the area of the country served by the sanatorium is less acute than it was in the past. Dr. Goodwin attributes this apparent increase among the population of resistance to tuberculosis to the cumulative effects of the anti-tuberculosis schemes throughout the country.

Medical Treatment of London School Children.

The arrangements for the medical and dental treatment of London school children for the year commencing April 1st, 1930, which came before the London County Council on November 12th, are necessarily influenced by the fact that from the date mentioned all the institutions of the Metropolitan Asylums Board and of the guardians will be transferred to the council, and it will be necessary to review all the available accommodation and to consider how such accommodation can be utilized to the best advantage, having regard to the various services which the council carries out. The possibility will need to be explored of making use of some of the accommodation in the transferred institutions for the treatment of school children, including the in-patient treatment of children suffering from enlarged tonsils and adenoids, but some considerable time must elapse before a comprehensive survey can be completed. The arrangements now made are those not likely to be affected by the altered conditions, and in making these, regard has been paid to the needs of the existing centres in the light of the attendances during the six months ended September 30th last, when 138,478 children received treatment, as compared with 128,863 during the corresponding period in the previous year. Under the approved scheme, four supervisory centres for the treatment of rheumatic children have been in operation during the year, and another has been authorized, but has not yet commenced. The experiment has proved very successful, and the parents are said to have greatly appreciated the opportunity of getting advice in the treatment of their children. It is proposed that an additional centre shall be established forthwith (at Woolwich), and that five additional centres shall be authorized for next year. The estimates for 1930–31 provide for the treatment of 40,940 cases of refraction and eye diseases, 17,860 ear, nose, and throat cases, 664 cases of ringworm, 77,890 cases of minor ailments, and 144,100 dental cases, as well as for the establishment of additional centres, one for minor ailments, one for dental cases, one for special ear cases, one for stammering children, and five for rheumatism. The cost will be £111,774 (of which dental cases account for £49,725), representing an increase of about £6,000 on the expenditure authorized for the current financial year.

Epsom College.

A vacancy has arisen for a Leopold Salomons entrance scholarship of £50 a year, open to the sons of legally qualified members of the medical profession either living or deceased. Those may apply (*a*) who were over 11 years and under 14 years of age on January 1st last; (*b*) who can show an adequate standard of education for their

age; and (c) whose financial condition is such as to make it impossible or difficult to obtain an education at Epsom College without the help of the scholarship. A vacancy has also arisen for a Sir Walter Buchanan scholarship of about £38 a year. It is primarily intended for the sons of deceased or prematurely invalided officers of the Indian Medical Service, but, failing any such candidates, it may be granted to the sons of legally qualified medical men of pure British parentage in necessitous circumstances who have practised medicine for at least five years in India. Forms of application for both scholarships may be had from the secretary, Mr. J. Bernard Lamb, 49, Bedford Square, W.C.1. All applications must be forwarded by the morning of December 4th.

Central Midwives Board.

The Central Midwives Board for England and Wales met on November 7th. A special penal meeting was held, followed by the ordinary monthly meeting. Business dealt with by the standing committee included a letter from the Colonial Office, enclosing a copy of a dispatch from the Governor of the Gold Coast, asking for recognition of a Midwives Board for the Gold Coast as competent to supervise examinations and to confer certificates, and of the Maternity Hospital, Accra, as a teaching school for midwifery. It was resolved to inform the Colonial Office:

1. That the establishment of a Midwives Board in the Gold Coast is not a matter for the Central Midwives Board. Should it be desired to establish a Board in that colony, the Central Midwives Board suggests that the procedure adopted by the various States in Australia and New Zealand might be considered by the Gold Coast authorities. The Central Midwives Board has no power to recognize a Board in the Gold Coast which would have the power to hold examinations on behalf of the Central Midwives Board and to issue its certificates.

2. That the present practice of the Board is not to approve training at institutions outside the British Isles; as it is of opinion that such training institutions cannot be considered to be satisfactory, inasmuch as they are outside the Board's jurisdiction, and the Board has no power to inspect them, and the circumstances of training outside the British Isles necessarily differ widely from those affecting pupils who are trained in the method of working under the Midwives Act.

Consideration was given to the question whether three years' general training undergone at the Lindlahr Sanatorium, Chicago, and the Norrkopping Hospital, Norrkopping, Sweden, entitled candidates to enter for examination on a reduced period of midwifery training. It was agreed that the Board should not approve, for the purpose of admission to examination on a reduced period of midwifery training, general training taken in a hospital outside the British Empire.

Correspondence.

ROYAL MEDICAL BENEVOLENT FUND CHRISTMAS GIFTS.

SIR,—It has been the practice of the Royal Medical Benevolent Fund for many years to give a Christmas gift to each annuitant and some of the most necessitous of the grantees. Both the annuitants, who are over 60 years of age, and the grantees are deprived of those little amenities of life which the more fortunate of us enjoy.

Many of our beneficiaries are alone in the world, as their friends and relations have passed over, and consequently they will not receive any gift or extra comfort this Christmas. Last year the Fund gave to each 30s.; this meant an expenditure of £500. Many of your readers will wish that the recipients of this gift in former years should not be deprived of it this year. But unless I am favoured by a generous response to this appeal our funds will not allow of this gracious and friendly act.

Will every reader of this letter please consider if he or she cannot send to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, London, W.1, a Christmas donation. I shall be grateful, whether the donation be large or small.—I am, etc.,

THOMAS BARLOW,
President.

November 15th.

THE TREATMENT OF HYPERPIESIA.

SIR,—In Dr. Douthwaite's address on the treatment of hyperpiesia (*British Medical Journal*, November 9th, p. 844), he states that he had never found iodides of help in cases unassociated with syphilis, and that enormous doses are required, while the digestive disturbances produced are most objectionable.

I think it is possible Dr. Douthwaite may have observed, but has forgotten, the remarkable and rapid action of small doses of iodides in the hyperpiesia of chronic or neglected hyperthyroidism in the fourth or fifth decade of life. This condition is sometimes associated with anginal symptoms, which also promptly subside and vanish. There is, in my experience, no more certain remedy, but were large doses to be used in these circumstances exacerbation, and not relief, of symptoms, would no less certainly ensue. In another respect the advantage of small doses of iodides and the failure of large doses is well known also in the treatment of certain phases of bronchitis cases.

Dr. Douthwaite also says, "Thyroid extract is seldom helpful except in the obese menopausal patient." To this statement the qualification should be added that in these circumstances thyroid extract may raise the blood pressure and produce angina pectoris. Means has already pointed this out, and it will be readily understood that as thyroid hormone stimulates metabolic activity, increases the heart work, and often does raise the blood pressure, extreme care must be employed in the dosage for cases of menopausal hyperpiesia. Patients suffering from menopausal hypothyroidism without hyperpiesia are, in my opinion, better subjects for thyroid treatment, and better still are those in whom the blood pressure is below the average normal. Suitable dosage gradually improves the heart muscle, the blood flow, the blood pressure, and metabolism. Dangerously toxic doses do reduce blood pressure, but the practice of giving such doses has been condemned.

Although any dietetic or other suitable plan which reduces obesity will tend to diminish hyperpiesia, I am not convinced that hyperpiesia is ever an indication for the use of thyroid extract, or that the treatment of the obese hyperpietic by this means is without danger.

From observations made by myself I conclude that the action of thyroid extract is to raise the systolic pressure, while the diastolic pressure may also rise, remain steady, or fall. The invariable effect is an increased pulse pressure.—I am, etc.,

JOHN EASON.

Edinburgh, Nov. 12th.

PHYSICAL TREATMENT OF RHEUMATISM: THE ANALOGY OF RADIUM.

SIR,—The statement of the Radium Commission published in your issue of November 16th (p. 911) concludes with a necessary warning.

"*Skilled handling essential.* What is required at the moment is work, intensive work, on the many problems which present themselves, combined with careful documentation of the methods used and registration of the results obtained. This calls for the close co-operation of physicists, clinicians, radiologists, and pathologists."

The warning might well be extended. What is treatment by radium but one of the many methods by which the disordered human body is brought into effective contact with the energies of nature? I suggest that a rule of practice that is true for one member might well be applied to the entire family. All thoughtful observers know that these primeval energies are essential to life, and in many conditions of disease invaluable in medicine. But those who know them best know too well that they may hurt or heal.

One of the consequences of the increased attention that is now being paid to rheumatic diseases is an epidemic of advertisements vaunting this and that form of external treatment. In many of these methods, which are of considerable value, heat or light plays the predominant part. Those who have worked most with these agencies in rheumatism will agree that, as with radium, so with heat and light, a close investigation of their action in different forms of disease and a documentation of methods and results are greatly needed, and that knowledge so

obtained is the prerequisite of good practice. How could it be otherwise?

My view of physical treatment is in close accord with that of leading authorities in Europe and America, who deplore the present low standard of treatment in all countries. The ignorance and carelessness in the use by many non-medical persons of physical remedies of all kinds—heat and movement in air and water, electricity and light—and the lack of special teaching and qualification for medical men who desire to employ them, have placed a great branch of therapeutics in an unsatisfactory position. There is everywhere an undesirable conflict of views. The "natural" methods of treatment, as they are sometimes called, encounter scepticism from the medical profession, whilst they are welcomed with undiminished faith by the public who have recourse to them. The physical physician, whilst lamenting the lack of precise knowledge, is inclined to give his vote for the patient.

The new movement in many countries for the study and treatment of rheumatic diseases furnishes an opportunity for placing physical treatment on a more authentic footing. Those who have been closely identified with this movement are profoundly impressed with the physical element in the causation and treatment of these diseases, and are resolved that so far as their influence extends the physical treatment of rheumatism for the people at large shall be properly organized and placed in the hands of medical men who are trained in its use. I have elsewhere expressed my own view that heat, properly dosed and spaced and localized in its application, is a master treatment of many of the conditions which are called "rheumatic," but only in skilled hands. For this reason I welcome the warning of the Commission in a nearly related field of treatment: "It cannot too strongly be emphasized that in unskilled hands (that is, in hands not fully trained in the best standards of technique) radium may be highly dangerous." I submit that the same warning applies to all physical remedies, whether given singly or in combination, in the treatment of rheumatism, substituting for the last words "ineffective or injurious."—I am, etc.,

R. FORTESCUE FOX,
Chairman of the Ligue internationale contre le Rhumatisme.

London, Nov. 16th.

THE CONSTITUTIONAL FACTOR IN EPILEPSY.

SIR,—With regard to the constitutional factor in epilepsy Dr. Kinnier Wilson[1] said, "Twenty-one years of practice and hospital experience have long since convinced me that the hereditary factor is persistently overrated, and the personal or constitutional factor underrated." This is exactly what for years I have been trying to say in respect of asthma, and, though with much less experience of it, I can say the same for epilepsy. Dr. Ryle[2] criticizes Dr. Kinnier Wilson's statement, both as to the manner of expression and as to the fact.

As to the manner of expression. It is a burglarious use of language to make "constitution" a synonym for "heredity." What right have geneticists to rob a good word which connotes more than heredity? Constitution depends on heredity, nurture, and infection, and the immunity or sensitization resulting therefrom. If the geneticists doubt this let them read Richet. As to the fact. Dr. Ryle says, "It is impossible to exclude epilepsy from among the constitutional disorders." Agreed; but a hereditary factor holds of all diseases, 100 per cent. of them. The point is the weight to be allowed for the hereditary factor, not only in a given disease, but in a given case. In human beings the factors nature and nurture are so inextricably mixed that it is difficult to assess them. That geneticists are apt to forget this is shown in Dr. Ryle's next sentence: "Dr. Kinnier Wilson's epileptic twins supply one of the strongest arguments in favour of the influence of the germ-plasm." Who would deny that? But does he forget that they had the same granny—two, if he likes—and that the dear old lady would in her impartiality be likely to stuff as many chocolates into Tweedledum as into Tweedledee?—that both would be brought up in the same way by the mother, and probably a vicious way, as the fits indicated?

Many years ago I was asked to treat a boy for fits. Dieting and a regular mercurial stopped them. A year or two later I was asked to treat his younger brother for the same thing; same treatment, same result. Both are now healthy men; no "hereditary" history. I can adduce other similar cases without family history of epilepsy. Possibly the heredity told in favour of fits rather than of some other manifestation of evil nurture, but that is all that can be said. If we take the two factors, nature and nurture, alone and allow 10 for the total weight, then in the case of asthma nature would always get less and nurture more than 5; and if we add infection and its consequences as a third factor, then nature 2, nurture 5, infection 3, would probably be near the truth, but the figures would vary with the case, and something similar might be said of epilepsy.—I am, etc.,

JAMES ADAM.

Glasgow, Nov. 16th.

[1] *British Medical Journal*, October 26th, p. 745.
[2] Ibid., November 2nd, p. 830.

POTENTIAL EPILEPSY.

SIR,—I seem to have come across lately more "fainting attacks" than usual. In a great many of these cases in my surgery, in public buildings, at vaccinations, etc., which I have met, there is pallor, a short loss of consciousness, and twitching of the limbs, face, and eyes. If epilepsy can be called the habit of discharge exhibited by neural mechanisms, that habit must have a beginning, often in a child with dyspepsia, and generally when the blood tension is lowered. I am afraid that we do not follow up the histories of these cases which show such minor nervous disorders. But it is possible to consider the wisdom of classing such cases as potential epilepsies, to give them a course of bromides, and warn the relatives to be on the look-out for further phenomena. I have always assumed that the bromides quieten the excitability of the cerebral cells, and have been frequently distressed at the lack of perseverance epileptic patients show in continuing their treatment long enough.

There seems a tendency to-day to substitute newer drugs, notably luminal, for the bromides, but my experience in practice, and from a study of responsible collections of results, suggests that this experimental medication is not warranted except by those who have the opportunity of treating epilepties in large numbers.—I am, etc.,

H. M. RAVEN, M.R.C.S., L.R.C.P.

Broadstairs, Nov. 12th.

RELIEF OF PAIN IN LABOUR.

SIR,—I should like to support Dr. Curnow Plummer's remarks in the fourth paragraph of his letter on the relief of pain in labour (November 16th, p. 933). I am convinced that it is the memory of the first terrible experience of labour which makes the young married woman say "never again," and even take all means in her knowledge and power to avoid the continuance of pregnancy. This seems one of the strongest arguments in favour of easing the pain of labour in primiparae. It is unnecessary to stress the immediate and remote pathological results of abortion, particularly if actively procured.

Might I suggest that in avertin we have an analgesic which goes a long way to help in this matter. The technique is simple. My patients are usually admitted to hospital in labour, and after an enema has been given I allow a primipara to have several strong contractions, in order that she may appreciate the relief which she is to get. Then a quarter grain of morphine is given, and the patient usually becomes drowsy and the contractions weak; but they are still strong enough to make the cervix dilate. Later, strong contractions return, with a tendency to bearing down, and examination per rectum will easily show that the head is coming down and the os is two thirds dilated. Not until this stage is reached do I give avertin. I give rather less than 0.1 c.cm. per kilo of body weight, which has to be guessed in the case of a patient admitted in labour. I wait until the passing of a strong, long pain, and immediately insert a small catheter per rectum. The administration is usually complicated by the onset of a pain about half-way through, but strong

pressure on the anus will prevent loss of more than an ounce or so, and thereafter no trouble is experienced. The patient immediately becomes drowsy, and remains so between pains. The administration of a little ether during the last three or four contractions is the perfect culmination of this method, but I can rarely find time to give it. I have had no complications so far.

The advantages of this method are these. The attendance of the doctor is required for the ordering of morphine, say five minutes, and again for the administration of the avertin, and thereafter for a short period, say half an hour. He need never appear again in a normal case, unless it is to give the final ether. The difference to a patient thus treated and one who is left "to get on with it" is dramatic. Actual pain is not abolished, and the contractions are not affected in any way, but the patient can look forward to her next pregnancy with equanimity instead of with terror.—I am, etc.,

Birmingham, Nov. 17th. J. S. M. CONNELL.

"ACTIVATED" FLUORESCEIN IN THE TREATMENT OF CANCER.

SIR,—There is nothing in Dr. Monckton Copeman's reply (November 16th, p. 929) to my letter of August 24th (p. 367) to lead me to retract any of my general or detailed criticisms there. To my mind he has entirely failed to prove that the use of fluorescein gives any better results than *x* rays or radium used alone. A relatively simple field in which to test its value is that of corneal ulcers having ultra-violet or *x*-ray treatment. Birch-Hirschfeld in recent articles has warned that its use is difficult and the results uncertain. How much more is this likely to be the case in malignant disease!

Dr. Copeman and his collaborators seem to ignore the fact that there is already a considerable literature abroad on the use of eosin, erythrosine, fluorescein, methylene blue, acridin, quinine, and other fluorescent agents as supplementary to radiation in malignant disease. Werner[1] has summed up this and all the other combined methods conveniently; the fluorescent substances have been found to have no practical value. I have myself, or in collaboration (*pace* Dr. Copeman), tried fluorescein, potassium, iodine, arsenic, lead, bismuth, and other heavy metals—only in one case where a bismuth emulsion was injected *below* a prominent supraclavicular node did there appear to be a definite result due to the secondary radiator. (The fluorescein was tried over a year ago at Mr. Shorney Webb's request.) Holthusen[2] sums up a long research on the effect of secondary radiation on bacterial cultures by saying that the hope that secondary radiators may be of use clinically, even in skin diseases, is "illusory." It is so because the gain in secondary electron-radiation is offset by its great absorption in the thinnest layers—even the chitin envelope of ascaris eggs is protective; also there is a lessening of the primary radiation in the deeper layers of tissue.

Finally, I cannot but think that Dr. Gouldesbrough has some unique method of measuring his "pastille doses" if he finds no erythema following the use of his dose of a "three-quarter Sabouraud B pastille (placed on the skin), all the rays having passed through a 4 mm. filter";[3] this equals a three-pastille dose at the half distance—a large dose, almost always causing an erythema! Nor can I think that the references to the chemical form in which the fluorescein is used—for example, "bad results and good results, thought to be due to differences in the *x*-ray apparatus employed, have no doubt really depended upon the form of the fluorescein used"[4]—show a due appreciation of the physical principles involved. Apart from toxicity, what is important in the use of an optical sensitizer is the atomic constitution, not the chemical combination, of the radiator.

I fear that the results in malignant disease, in so far as they are attributed to the fluorescein, are in the main "illusory"; and any further critical work here on the subject will lead to this conclusion, which was reached five years ago, after research and twenty years' study of the literature on various aspects of the subject, by Werner, Rieder, and other workers abroad.—I am, etc.,

TERMINOLOGY OF THE LEUKAEMIAS.

SIR,—In medical literature the word "leukaemia" has long displaced "leucocythaemia," but some sticklers still insist on writing "leuchaemia." However, if one considers "leukaemia" merely as the result of conveniently shortening leuk(ocyth)aemia no possible objection to its employment can be maintained. Not so in regard to the term "aleukaemic leukaemia," in which the adjective negatives the substantive. The usual way of avoiding this terminological difficulty is to call myeloid leukaemia "myelosis," and lymphoid leukaemia "lymphadenosis," and subdivide them, according to the total white cell count at the time of observation, into (1) aleukaemic myelosis; (2) leukaemic myelosis (the original cases of "splenomedullary leucocythaemia"); (3) aleukaemic lymphadenosis; and (4) leukaemic lymphadenosis. This subdivision is certainly the simplest one, but I would suggest substituting the adjective "hypoleukaemic" (that is, hypoleucocythaemic) for "aleukaemic," and "hyperleukaemic" (that is, hyperleucocythaemic) for "leukaemic." Either of the two leukaemias may be temporarily or persistently hypoleukaemic or hyperleukaemic. Cases with medium counts (between hypoleukaemic and hyperleukaemic) could be reckoned as myelosis or lymphadenosis without any qualification.—I am, etc.,

London, W.1, Nov. 12th. F. PARKES WEBER.

GLUCOSE IN THE TREATMENT OF ASTHMA.

SIR,—I am anxious to avoid making any claim for priority in the discovery of a treatment of asthma by glucose. The relative intolerance of many or most nervous asthmatic children for fat and their high need for sugar has been known for a long time. My former assistant in the Children's Department at Guy's Hospital, Dr. Osman, has, no less than myself, been an advocate of sugar and glucose, and first suggested the name of "glycopenia" for the condition under consideration. His work on the subject has influenced all the teaching in the department. —I am, etc.,

London, W.1, Nov. 19th. H. CHARLES CAMERON.

ASTHMA AND NEURASTHENIA.

SIR,—Dr. Hurst's statement (November 16th, p. 930) that Dr. H. C. Cameron discovered a glycopenia (or hypoglycaemia) in asthmatics is of interest, but will cause a little bewilderment in those who have followed Dr. Cameron's work. We first hear of Dr. Cameron advocating the use of glucose in highly strung children who are liable to become neurasthenic. It is evident that in transferring this treatment to asthmatics he recognizes that the basis of asthma is neurasthenia. I strongly advocated this view at the Manchester meeting, but it was ignored by Dr. Hurst.

The only difference that I can find between an ordinary neurasthenic and an asthmatic is that in the asthmatic there is vagal irritation from the nose and throat. At Manchester I advocated the treatment of the nose and throat, and the treatment of the neurosis with suitable sedatives, which are those acting on the nervous system alone, such as bromide, luminal, medinal, and in some cases chloral. This is a successful method of treatment. In my experience adrenaline and ephedrine should be used sparingly and only in acute attacks of asthma, because they cause fluctuations in the vasomotor control, whereas what is most needed is *stability*. This clinical experience rests upon a strong physiological foundation.—I am, etc.,

London, W.1, Nov. 17th. H. MORTIMER WHARRY.

EOSINOPHILIA IN ASTHMA.

SIR,—In the reports of recent discussions on asthma I have been surprised to find no attempt at distinguishing between cases of this disease with and without eosinophilia. It is known that patients suffering from asthma may have an increased number of eosinophile cells in the blood, and considerable numbers of these cells in the sputum. There are, on the other hand, cases in which this feature is completely absent. Whether they also differ in any clinical respect I am not in a position to say.

A fact which does not appear to have found recognition is that the sputa in these two types of the disease also differ bacteriologically. In the non-eosinophilic type there is almost invariably clear evidence of an infection (the organism being usually either *B. pfeiffer* or a pneumococcus). In the eosinophilic sputum, commonly consisting of highly gelatinous clear mucus containing thin white strands of muco-pus in which quite 50 per cent. of the leucocytes are eosinophils, films are devoid of organisms, and cultures, if made from clean material, are almost sterile. I have only once obtained a pure growth of a pathogenic organism by ordinary cultural methods from sputum of this kind, and then in numbers so small in relation to the quantity of material sown that its significance was doubtful.

I do not wish to enter upon any general discussion as to the etiology of asthma, but I submit that from the cytological and bacteriological standpoint there are two varieties of the disease. The non-eosinophilic is accompanied by an infection, and its recognition is of importance because the disease is then susceptible to specific treatment. The eosinophilic variety is apparently non-infective, and patients whose attacks are excited by foreign proteins presumably fall into this group. I suggest that an examination of the sputum should be regarded as essential in investigating a case of asthma, both as a guide to treatment for the individual patient, and because the significance of any observations, whether clinical, biochemical, or therapeutic, would be clearer if it were known to which variety of the disease they refer.—I am, etc.,

London, W.2, Nov. 18th. LAWRENCE P. GARROD.

THE BASOPHIL CELLS IN ERYTHRAEMIA.

SIR,—In his interesting paper on erythraemia with jaundice (November 16th, p. 892), Dr. F. Parkes Weber gives the white cell count as 16,350 per c.mm., with polymorphonuclears 70 per cent., basophils 3 per cent., eosinophils 3 per cent., lymphocytes 21 per cent., and monocytes 3 per cent. Now the point is that the white cells are doubled, the polymorphs and lymphocytes doubled, the eosinophils and monocytes just a high normal count, and yet the masts (basophils) are increased seven times—that is, up to 490 per c.mm.

In 1918, in a case of acholuric jaundice, I found a total white count of 7,000 per c.mm., with 3 per cent. of masts. Considerable increase of masts is so rare that this excited suspicion. Eventually I convinced myself that 2 per cent. of these were leucoblasts, which are quite distinct from masts. Accordingly, when I recognized my first case of splenomegalic polycythaemia, I was able to identify leucoblasts in the films, sometimes to the number of 3 per cent. of the whites. Indeed, I have not seen these cells so numerous except in splenomedullary leukaemia, though they are always present in pernicious anaemia. Nevertheless, mast cells are often in evidence in my case of erythraemia, so that the leucocytosis is really a granulocytosis showing myelocytes of all three granular forms, as well as leucoblasts.

I may add that in 1928 erythroblasts began to appear, along with anisocytosis, polychromasia, and punctate basophilia. These have remained. For four years (1923–26) the man suffered from the disease; but the red count then fell at the rate of a million a year, and is now 4,900,000, the haemoglobin percentage being 92. For over twelve months he has had excellent health; yet his spleen now reaches below the umbilicus, and, in spite of normal red count and colour index, one must call him anaemic.—I am, etc.,

West Ealing, Nov. 17th. R. CRAIK.

BACTERIOLOGY OF TONSILS IN RELATION TO ACUTE RHEUMATISM.

SIR,—The recent correspondence on this subject prompts me to suggest that acute rheumatism might be grouped into stages comparable to the stages of syphilis.

Primary.—An acute upper air passage infection, probably carrier-borne, observed in semi-isolated communities as epidemic sore throat and tending to be endemic during the troughs between epidemics.

Secondary.—After an interval of a few days to two or three weeks the typical attack of acute rheumatism, subacute rheumatism, or pre-rheumatic symptoms.

Tertiary.—Residual fibrosis. (Aschoff's bodies; subcutaneous nodules.)

Para-rheumatic.—Chorea and perhaps erythema nodosum.

As in syphilis, the causal organism will be present in the primary stage. After this it will become increasingly difficult to find. Unlike the spirochaete, it produces but a temporary immunity, if any. Recurrence must therefore be looked for whenever the infectious sore throat is epidemic. The organism may be absent from the nasopharynx between attacks. The immune carrier hypothesis[1] and the secondary nature of the rheumatic attack (whether the susceptibility is allergic or not[2]) explain family tendency, environmental factors, and, in part, class incidence. Bloomfield and Felty's[1] beta haemolytic streptococcus is one of many strains producing sore throats in epidemics. The epidemics vary with the specific strains. Haig-Brown's little book on tonsillitis,[4] when its material is interpreted in the light of more recent knowledge, is well worth reading in this connexion, and Bezançon and Weil's[3] summary of the literature on the epidemic nature of acute rheumatism in their communication to the Bath Conference on Rheumatic Diseases, 1928, is very suggestive. The only two cases of acute rheumatism I have seen in my small practice during the past four years occurred within fourteen days of each other, during an epidemic of sore throat. These epidemics are surface infections—the organism is not confined to the tonsil, but the whole of the nasopharynx is the portal of entry. Of the two the nasopharynx is more important, and it can be shown that tonsillectomy has little control over the recurrence and incidence of acute upper air passages infections. Tonsillitis is merely a symptom of these droplet infections. In this I believe Dr. Cronin Lowe[5] will agree with me, but I suggest that pathogen-selective cultures will only be of value during the primary and secondary stages, and I would remind him of the difference between surface and tonsil puncture cultures.

I also agree with Drs. Nabarro and MacDonald[6] that probably many strains of streptococci can produce the specific poison; but if the suggested analogy with syphilis could be substantiated would they amputate the penis as prophylaxis against the spirochaete? Tonsillectomy for *acute* rheumatism is hardly less rational.—I am, etc.,

Stratton-on-the-Fosse, nr. Bath, Nov. 10th. W. H. BRADLEY.

TREATMENT OF GASTRIC AND DUODENAL ULCER.

SIR,—Eighteen months ago a gastric ulcer which had resisted medicinal treatment for over six months was healed after a three weeks' course of feeding through a duodenal tube, retained *in situ* during that period.

Yesterday my stomach and duodenum were examined after an opaque meal and found to be normal. Returning home I read in the *British Medical Journal* the report of a discussion on "Gastric and duodenal ulcer: results of treatment" (November 16th, p. 907), but found no mention of the method whereby ulcerated areas are put out of action by feeding through the duodenal tube. The simplicity and effectiveness of this method should appeal both to the physician and to the patient; when it is more generally adopted it should remove many cases from the domains of surgery.—I am, etc.,

EPHEDRINE IN GALL-STONE AND RENAL COLIC.

SIR,—In December, 1928, I was called to see an old lady suffering intense pain from gall-stone colic. I tried morphine, atropine, bismuth, and sodium salicylate and belladonna, but without giving her any relief. It occurred to me that as ephedrine does good in asthma and hay-fever it might, by its action on striped muscle, relieve spasm elsewhere. I therefore gave 1/2 grain of ephedrine hydrochloride (B.W. and Co.), and was gratified to see relief of pain in the course of a few minutes. I might add that the patient was at the time under treatment for gall-stones at one of the leading London hospitals.

About ten days ago I was called to see a man in great agony, suffering from renal colic. I tried 1/2 grain of morphine, with no result, and then gave him 1/2 grain of ephedrine hydrochloride with immediate relief. In case it might be thought that it was the morphine that gave relief, I would add that another attack of intense pain came on four hours afterwards, which again was immediately relieved by ephedrine hydrochloride. I then sent the patient to the Metropolitan Hospital, where he was examined by Dr. J. W. Linnell, who admitted him to hospital, and has kindly informed me that the patient passed an oxalate stone a few days later.—I am, etc.,

London, E.8, Nov. 17th. ARTHUR J. AMBROSE.

ARSENICAL IONIZATION.

SIR,—With reference to Dr. Scaife Armstrong's letter in the *Journal* of November 16th (p. 933), I am not aware that arsenic behaves in a different manner electrically from any other salt in solution. If a pad soaked in 1 per cent. sodium arsenite were placed on the skin I should expect that the arsenic ion would be introduced by applying the negative pole of the continuous current. We all know that arsenic is a very toxic body, and I am not surprised to hear that severe reactions were obtained as a result of this form of medication, and it would appear most probable that these reactions were directly due to the introduction of the arsenic ion.—I am, etc.,

Ipswich, Nov. 18th. C. H. C. DALTON.

Obituary.

THOMAS HORROCKS OPENSHAW, C.B., C.M.G., M.S., F.R.C.S.,

Consulting Surgeon to the London Hospital and the Royal National Orthopaedic Hospital.

THE late Mr. T. H. Openshaw, whose death took place on November 17th, after some weeks' illness, was a Lancashire man who, owing to a family connexion, was educated at Bristol Grammar School, on leaving which he began to train as an engineer. He did not pursue that calling for long, but exchanged it for the study of medicine at the London Hospital, from which he proceeded to the membership of the Royal College of Surgeons in 1882, and the Fellowship in 1886. His other qualifications were L.S.A. 1882, L.R.C.P.London 1884, M.B.Durham 1883, B.S. 1885, and M.S. with honours from the same University in 1887. After holding the usual house offices he was elected assistant surgeon to the London Hospital, and in due course surgeon to out-patients, full surgeon, and, on superannuation, consulting surgeon. As assistant surgeon to Mr. Waren Tay, who confined his interest mostly to ophthalmology, Openshaw had unusual opportunities, for Mr. Tay's beds were practically at his disposal. Of these opportunities he made good use, and perfected his technique as an operator. He for some time held the post of lecturer on anatomy, and at a later period on surgery. In 1916 he was elected a member of the Council of the College of Surgeons, on which he sat until 1924. In 1893 he was elected assistant surgeon to the National Orthopaedic Hospital, which institution was afterwards amalgamated with the Royal Orthopaedic Hospital under the auspices of King Edward's Hospital Fund. From that date he took a keen interest in the treatment of deformities, and when the orthopaedic department was formed at the London Hospital it was placed under his charge, and remained so until his retirement from the active staff.

Openshaw had long taken an interest in military surgery as an officer of a volunteer bearer company, and, after the formation of the Territorial Army, of the R.A.M.C.T. He was surgeon to the Lincolnshire Yeomanry, in which he rose to the rank of lieutenant-colonel. When the events of the war in South Africa called for great reinforcements and the Imperial Yeomanry Field Hospital was formed and sent out under Colonel Stonham (surgeon to the Westminster Hospital), Openshaw was one of its staff. He left it, however, after the capture of Pretoria, and became principal medical officer of No. 2 Model School Hospital at that place, in which office he had a freer hand and better opportunities of doing good work than he had in a subordinate position with the Yeomanry hospital. Of these opportunities he fully availed himself. On his return to London after the cessation of regular hostilities he found, like some others, that practical patriotism such as his did not pay, for he had to build up his private consulting practice afresh. The days had gone when a distinguished surgeon could rush out in a blaze of publicity to the seat of war, do a number of spectacular operations, and return in six weeks with an enhanced reputation. But Openshaw's solid merit could not be long overlooked, and he soon recovered his practice.

When war was declared in 1914 Openshaw was not included in the scheme of Territorial and other hospitals on the staffs of which many of his colleagues found themselves in important positions. The somewhat remarkable scheme for the formation of a great naval hospital near Edinburgh, to be staffed by London men, included him, and when this idea failed to develop into reality he was temporarily without any position such as his experience and capabilities deserved. At the London and the Orthopaedic he, like the rest of their staffs, treated the wounded who replaced so many civilians in their wards. An opportunity of special usefulness soon offered itself, however. In 1915 it was brought to the notice of a wealthy and philanthropic lady, Mrs. Gwynn Holford, that the old defective methods of supplying war amputees with artificial limbs had broken down. The Commissioners of the Royal Hospital at Chelsea had hitherto supplied prostheses of this sort through instrument makers, without expert surgical advice. Even this imperfect method broke down under the strain of the thousands of cases needing attention. Mrs. Holford was properly advised to consult an orthopaedic surgeon, and accordingly was introduced to Mr. Openshaw. As the result of her enthusiasm and indomitable energy, Queen Mary's Convalescent Auxiliary Hospital Committee was formed, and Roehampton House, then in the hands of the builders, was borrowed from Mr. Kenneth Wilson. In all the questions which arose, as to the best kind of limbs to be supplied and the choice of makers who should supply them, Openshaw's advice was sought and taken, and most of the orthopaedic surgeons who joined him as colleagues as the work increased were appointed on his recommendation. The hospital was opened in July, 1915, and it is well known that it was a great success and served as a model for many of those which were afterwards established in different parts of the United Kingdom for the supply of artificial limbs.

Meanwhile his experience and abilities as a consultant were not neglected. He was appointed consulting surgeon to the Eastern Command, with the rank of colonel, in which capacity he had to visit a large number of auxiliary and other hospitals in the East of England, and to spend much time in travelling. When in 1918 the foundation of the British Orthopaedic Association was mooted, he was one of the three signatories of the circular letter calling together a preliminary meeting, the others being Sir Robert Jones and Mr. Muirhead Little. He declined office in the association, however, and took little or no part in its subsequent meetings, but he was at one time president of the Orthopaedic Subsection of the Section of Surgery of the Royal Society of Medicine, and took part in many of its meetings and of the Section which it ultimately became. He was a vice-president of the Section of Diseases

of Children, which included orthopaedics, at the Annual Meeting of the British Medical Association at Liverpool in 1912, and president of the Section of Orthopaedics at Portsmouth in 1923.

Openshaw was not fond of using his pen. He wrote no book and contributed few papers to the medical press. His tastes were not literary. He had a blunt manner, made the more noticeable by that Lancashire accent which he never lost, but in an unguarded moment he would display, despite his native shrewdness, a disarming candour. If his colleagues found him a rather incalculable factor and sometimes wondered what "Tommy" would next be at, he was always popular and received a smiling welcome in whatever circle he entered. In his younger days he was a keen cyclist and he was always devoted to fishing. His other enthusiasms were for Freemasonry and the Shipwrights Company, of which he was a past-master, and at whose dinners his speeches were always well received.

Openshaw was a good operator. His sure anatomical knowledge and his quick decision in emergencies served him well. His service at the London bridged over the change from the antiseptic to the aseptic ritual in the theatre. Having achieved excellent results with antiseptic methods he was loath to change, and it was some time before he yielded to the innovation of operating in gloves, for his skin was unaffected by frequent immersion in 5 per cent. carbolic lotion. Being justly of the opinion that his powers were unimpaired he took his superannuation hardly, although it was in the usual course, and he bewailed the enforced cessation of his hospital work, but found some compensation in private practice and in making himself useful as the only medical member of the committee of the Royal Surgical Aid Society.

We are indebted to Mr. ROBERT MILNE, surgeon to the London Hospital, for the following appreciation:

The news that Openshaw had entered upon the Great Adventure must have come as a great surprise to very many members of the profession. His very robust, sturdy figure had been about town, and at the London Hospital old students' dinner only four weeks ago, with no suggestion of failing bodily or mental vigour. No one meeting him called him probably anything but "Tommy," so widespread was this shortening of his full name, and the universal use of the title marks the width of his popularity and the esteem he won on all hands. Many memories crowd upon one who has been in touch with him since he lectured us on anatomy, and who helped to shoulder him along the platform when he left for the South African war thirty years ago, but the outstanding feature about "Tommy" was his honesty of purpose and his loyalty. In council he spoke little, but he was right in his views. He was a sportsman all his years—when he played football, when he led parties of students to Ascot on a cycle—and his final illness came partly through his zeal to capture a pike in the West Country, and partly through his loyalty to keep a professional appointment when he was not really fit. His interests were always orthopaedic, and his out-patient departments were filled with children who loved him. He might not remember their names correctly always, but he remembered their special likes, and he always had an appropriate word for them. He had a wide experience even before radiographs were introduced and before the laboratory was important; he had trained himself to accurate observation, so that his clinical instinct in diagnosis and appropriate treatment was really wonderful. His lucid speech, with a Lancashire burr and dogmatic mien, made him such a popular and practical teacher that his Friday mornings attracted patients and students alike. He loved work and he loved his London Hospital. When one could get him talking his reminiscences were voluminous, for he was steeped in the traditions and the lives of the great surgeons, in the lore of surgery, and of the London Hospital. He was a keen Freemason, interested in the historical details and past of the city companies, and an energetic volunteer. In spite of all these activities, he was always available to help actively or by advice a professional colleague, and to stick by him through thick and thin. The loss of his son, to be followed soon by the loss of his wife, were two staggering blows which did not fail to leave their traces on him towards the end, but he accepted these losses with the courageous fortitude one associated with his character. He continued his work, he continued his fishing, but he slackened in his zeal. We shall miss his form, his cheery word, his tales and experiences, but his memory will be with us as the personification of honesty and loyalty.

Dr. HERBERT R. SPENCER sends the following tribute:

Many will mourn the loss of our dear friend T. H. Openshaw, commonly known as Tommy Openshaw or "Oppy." I believe he was a very skilful surgeon, I know he was an honest and kind one, and as a man he was one of the best. He had some grievous domestic losses, and of late his health had not been good. Yet up till near the end of his life he had a keen appreciation of the good things it offered, and the catholicity of his tastes as a sportsman was, I think, not surpassed by that of any member of our profession. Hunting, shooting, fishing in all weathers, he was equally keen on them all. With his friend Pockett—a good sportsman, who predeceased him—he would shoot all day, and then travel by motor through the night to another shooting or fishing next day, and his friends never ceased to marvel at the astounding energy he showed when he had passed his three-score years and ten. He was the beloved president of the Red Spinner Angling Society, to which he presented the challenge cup which he himself won outright in 1925. Some notable fish which were taken by his rod were a chub and barbel each weighing over 7 lb., a tench of 5 lb. 14 oz., a trout of 6 lb. 4 oz., and a pike weighing over 24 lb. He was especially fond of pike fishing, and was not deterred by the most inclement weather from its pursuit. On these occasions he used to wear an abundance of coats and wraps, which gave his short figure an imposing appearance. I think his ambition was to catch a "record" pike which should surpass the somewhat doubtful weight of Colonel Thornton's (said to have weighed about 48 lb.). On the last occasion on which I saw him he was meditating an attack on a monstrous pike in one of the Duke of Marlborough's lakes, which he had coveted for a long time. I hope he succeeded. In any case, his 24-lb. fish was no mean trophy. Openshaw was in every deed a sportsman. Take him for all in all we shall not look upon his like again.

FREDERICK MONTIZAMBERT, C.M.G., L.S.O., M.D.,

Formerly Director-General of Public Health and Sanitary Adviser to the Canadian Government.

DR. FREDERICK MONTIZAMBERT, the doyen of the public health service in Canada, died at Ottawa on November 3rd. He was born at Quebec in 1843, so that his long life spanned half the distance between the present day and the conquest of Quebec by General Wolfe.

After receiving his education at Toronto and at Edinburgh University, where he graduated M.B. and later proceeded to the M.D., Montizambert entered the Canadian Public Health Service at the age of 23. This was at the time of the so-called Fenian invasions, when raids by Irish bands were made from the American frontier, property was destroyed, and the lives of some Canadians were lost. Montizambert served during this period as principal medical officer of the Quebec military district, and received for his services a medal and clasp. Shortly afterwards he became medical superintendent of the St. Lawrence Service, a post which he held for a quarter of a century. A matter in which he greatly interested himself while in this position was the quarantine regulations, which had been unchanged for thirty years and were framed only with a view to conditions on sailing ships. On his initiative they were simplified and made more reasonable and up to date. He himself took charge of the quarantine service, both maritime and inland.

By the end of the century Dr. Montizambert had become known as the leading public health official in Canada, and was recognized internationally as an outstanding authority

on all matters appertaining to public health. After a period of five years as general superintendent of the Canadian Health Service, he became director-general in 1899. He was to the forefront in every sanitary movement. In 1900, when the Canadian Tuberculosis Association came into being he was one of the founders. A few years later the Canadian Branch of the St. John Ambulance Association was formed, with Dr. Montizambert as its first president. He was at one time president of the American Public Health Association and served for many years on its executive council; he was also an honorary fellow of the Society of Medical Officers of Health in this country. When the British Medical Association visited Montreal for its Annual Meeting in 1897 Dr. Montizambert was vice-president of the Section of Public Medicine, and on its second visit to Canada in 1906, when it met at Toronto, he was president of the Section of State Medicine. He retained his membership of the British Medical Association until 1921. In 1907–8 he was president of the Canadian Medical Association. He was also a governor and member of the executive council of the Royal Victorian Order of Nurses for Canada. All matters connected with first aid, Red Cross service, and public nursing had his hearty co-operation.

His services to Canada were recognized in 1903 by the award of the Imperial Service Order, and in 1916 by the bestowal of the Companionship of St. Michael and St. George. He enjoyed in an unusual degree the esteem of his profession and of his colleagues in the public service because of his kindly disposition, which endeared him to all with whom he came in contact.

We have to record with much regret the untimely death of Mr. D. M. B. Evans, F.R.C.S., which took place at Charing Cross Hospital on November 9th. Evans, who was surgical registrar to the hospital, had been playing Rugby football only a few days previously, and, following an injury to the heel sustained during the game, he developed a staphylococcal septicaemia, which proved rapidly fatal. He first joined Charing Cross Hospital Medical School in 1921, having completed his preliminary medical studies at the Cardiff Medical School, University of Wales. After a brilliant undergraduate career he took the diplomas L.R.C.P., M.R.C.S. in 1923, and graduated M.B., B.S.Lond. in 1925. In 1926 he obtained the membership of the Royal College of Physicians of London, and in 1928 the Fellowship of the Royal College of Surgeons of England. Immediately after qualification he became house-surgeon to Charing Cross Hospital, and then held a sequence of appointments as resident medical officer to Queen Mary's Hospital for Children, Carshalton; resident medical officer to Bolingbroke Hospital; demonstrator of anatomy at King's College, Strand; senior house-surgeon to All Saints' Hospital for Genito-Urinary Diseases; and, since March, 1928, surgical registrar to Charing Cross Hospital. In 1926 he contributed to the *British Medical Journal* a paper on hypertonic saline in chronic oedema, and in 1927 a paper to the *Lancet* on squamous epithelioma of the bronchus. He was a member of the British Medical Association. Baden Evans was an attractive and popular personality. It was said of him that whatever he turned his mind to he would certainly do well: he chose surgery, and though at the time of his death he was but in his 29th year, he was already recognized by those who saw his work as a surgeon of the greatest promise. Mr. Norman C. Lake, surgeon to Charing Cross Hospital, sends the following tribute: Charing Cross Hospital has lost one of its most brilliant students of recent years in the death of D. M. B. Evans. For the past two years he had identified himself very closely with the work of the hospital while he held the post of surgical registrar; indeed, it was probably his keen and constant application to the duties of that post which so reduced his resistance as to render him a ready prey to the septicaemia which so rapidly and tragically caused his end. His great ability was obvious to all and the future had much in store for him. The hospital, the whole profession, is the poorer for the loss of a life so full of promise, a skilful surgeon, a lucid teacher, a musician, and a sportsman.

Dr. EDWIN CLIMSON GREENWOOD, O.B.E., who died on November 7th, was born in 1851, and received his medical education at Guy's Hospital. He obtained the diplomas M.R.C.S., L.R.C.P. in 1886. For many years he held the post of public vaccinator for St. Marylebone, and was a well-known teacher of vaccination, holding an appointment under the Privy Council. For thirty-six years he was a divisional surgeon to the Metropolitan police, and retired on February last, when he was presented with an illuminated address. During the war he was in charge of the Acheson Hospital for Officers. Other appointments held by him included those of medical superintendent to the St. John and St. Elizabeth Hospital, visiting physician to St. Marylebone Almshouses, and honorary surgeon to the Portland Town Free Dispensary. He was a member of the British Medical Association, and contributed several papers to the *British Medical Journal*. Dr. A. E. Cope sends the following appreciation: It was in March, 1898, that I first met Edwin Climson Greenwood. Drs. Miskin, Jaynes, and I had organized a meeting of the London public vaccinators in view of the Vaccination Bill which was being introduced into Parliament, and which in the following August became the Vaccination Act, 1898. The meeting was held in the old St. Martin's Town Hall, immediately behind the site now occupied by the Cavell memorial. There was a full attendance, when, just before the time for the commencement of the proceedings, a tall, distinguished-looking man came striding in, and Jaynes, glancing up, said: "*Here's Greenwood; we must get him* in the chair." There was certainly no one in the room who looked more fitted for the position, and on being asked he consented, was elected president of the newly formed *Association of Public Vaccinators of England and Wales*, and held the office for ten consecutive years, with ability and distinction. In addition, he secured the services of his brother, Mr. Charles Greenwood, a solicitor, who, as organizing secretary, guided the affairs of the association successfully through the difficult years immediately succeeding the passing of the Act. Mr. Charles Greenwood died shortly after the war, and his brother gradually withdrew from active participation in the work of the association, though still retaining his interest in it, and occasionally attending its meetings. His colleagues will miss his kindly, gracious presence, and his loyal friendship.

We regret to record the death, at the age of 74, of Dr. GEORGE GRAHAM HODGSON, which took place on November 3rd at his home in Eastbourne. Dr. Hodgson received his medical education at Liverpool and at University College Hospital, London, taking the diploma M.R.C.S.Eng. in 1877. For a year after his qualification he held a resident appointment at the Rotunda Hospital, Dublin, and followed this with nearly two years as a ship's medical officer to the R.M.S.P. line. In 1879 he obtained the further diplomas of L.R.C.P.Lond. and L.S.A., and in 1902 he graduated M.D.Durham. For some years Dr. Hodgson engaged in private practice in Liverpool, where he was appointed honorary surgeon, and later consulting surgeon, to the Bootle Hospital. In 1896 he moved to Chertsey, Surrey, and there, until his retirement in 1920, he had a large country practice, in which, by his skill, simplicity, and kindness of heart, he won the esteem and love of all his patients. Dr. Hodgson had always been interested in the study of mental disorders, and during the three years immediately following his retirement he was assistant medical officer to the Mental Hospital, Ipswich. He was a member of the British Medical Association. His surviving son is Dr. H. Graham Hodgson, C.V.O., radiologist to King's College Hospital, who attended the King during his recent illness.

DR. THOMAS GALLIMORE, who died at his residence in Leamington on November 1st, in his eightieth year, received his medical education at Owens College, Manchester, and in 1884 obtained the diplomas L.R.C.P., L.R.C.S., L.M.Ed., and the L.S.A. After holding the posts of resident assistant physician at the Manchester Royal Infirmary and house-surgeon to the Metropolitan Hospital he travelled to China as a ship surgeon. His first practice was a small one

in Denton, which at the end of seven years became one of the largest general practices in Lancashire. He next spent five years in Lyme, Cheshire, and was visiting surgeon to Chester Infirmary and to the Chorlton Hospital, Withington. In 1894 Dr. Gallimore went to Rowington as the first resident medical practitioner there, and lived at the Manor House. He was appointed surgeon to a section of the Great Western Railway, and was also surgeon to the Shirley racecourse for twenty years. He removed to Leamington in 1914, and from 1916 to 1918 worked in connexion with the Northfield War Hospital. Dr. Gallimore was a member of the British Medical Association. He was a keen follower of hounds, and hunted with the Cheshire and the North Warwickshire packs.

We regret to record the death from pneumonia of Dr. ROBERT W. DALE, which took place on October 12th, in a Paisley nursing home. Dr. Robert Dale, who was in his fiftieth year, was a native of Paisley, and had received his early education in the John Neilson Institution and Grammar School, later proceeding to Glasgow University, where he graduated M.A. in 1901, and M.B., Ch.B. in 1905. Having held appointments as house-surgeon, and then as dispensary physician, to the Royal Alexandra Infirmary, he spent a year practising in Clydebank, and a year in England; and in 1907 he entered into partnership with his brother, Dr. John S. Dale, in Paisley. In this partnership, except for a break during the great war, when he served in Salonica as captain in the Royal Army Medical Corps, he was engaged until the time of his death.

The following well-known foreign medical men have recently died: *Dr. C. C. SICK, professor extraordinary of surgery at Hamburg, aged 72; Dr. FRIEDRICH LÜPKE, professor of pathology at Stuttgart: Dr. ANTONIN FRANK, professor of anatomy at Komuskcho, Czechoslovakia: Dr. VICTOR BLONDIAU, an oto-rhino-laryngologist of Charleroi; Dr. FLORIANO BAYMA, an eminent surgeon of Sao Paulo, aged 33; Dr. RICALDONI, who successively occupied the chairs of therapeutics, medical pathology, clinical medicine, and neurology at the University of Montevideo; Dr. ALEXANDRE RENAULT of Paris, formerly president of the Société de Dermatologie; Dr. JEAN WATELET of Vire, a pupil of Potain and friend and medical attendant of Barbey d'Avrevilly and François Coppée, aged 81; Dr. HENRI WOUTERS, a medical jurist of Louvain: and Professor FELICE ROSSI, a leading surgeon of Bologna.*

The Services.

QUEEN ALEXANDRA MILITARY HOSPITAL.

Opening of New Wing.

H.R.H. THE PRINCE OF WALES has consented to open the new wing of the Queen Alexandra Military Hospital, Millbank, at 12 *noon on Tuesday, November 26th.* Admission to the ceremony will be by ticket, except in the case of officers in uniform and their wives. Application for tickets should be made to the Officer Commanding, Queen Alexandra Military Hospital, Millbank, S.W.1.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on November 15th the following medical degrees were conferred

M.D.—R. H. Metcalfe, H. R. Youngman.
M.B., B.Chir.—G. C. Dewes, T. A. A. Hunter, T. S. Read, J. L. Newman.

Dr. W. E. Dixon, F.R.S., has been reappointed Assessor to the Regius Professor of Physic for the present academic year, and Dr. H. B. Roderick supervisor and examiner in surgery for the Third M.B.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting of the Royal College of Surgeons was held on November 14th, when the President, Lord Moynihan, was in the chair.

Diplomas of Membership were granted to 119 candidates, whose names were included in the list of those receiving the licence of the Royal College of Physicians printed in our issue of November 9th (p. 832). Licences in dental surgery were granted to 37 candidates.

Mr. Victor Bonney and Mr. Louis Rivett were appointed to give evidence before the Maternal Mortality Committee appointed by the Ministry of Health.

Mr. Victor Bonney was re-elected as a representative of the College on the Central Council for District Nursing in London for three years from January 1st, 1929.

A letter, dated September 11th, 1928, from the honorary secretary of the [illegible] was read, making suggesti[illegible] Examination for the [illegible] This letter was refe[illegible]

The President announced that Mr. Louis Baron had offered to endow a research scholarship of £500 a year for seven years, in memory of his father, Mr. Bernhard Baron. This offer was accepted with grateful appreciation.

It was decided that a reception in connexion with the jubilee celebrations of the British Dental Association should be held on Thursday, May 29th, 1930.

Macloghlin Scholarships.

The report from the committee c[illegible] was approved and adopted. The the regulations, amended so as to b[illegible] *the present regulations applicable to candidates* for the diploma of M.R.C.S.Eng., and a form of petition to be presented by candidates.

Regulations.

1. No person shall be eligible for a scholarship who is below the age of 16 or above the age of 22 years.

2. Candidates must be young men *studying and seeking to qualify* themselves as Members of the Royal College of Surgeons of England, whose conduct has been satisfactory, and who are in need of financial assistance in the prosecution of their studies.

3. The last day for sending in petitions shall be June 1st in each year.

4. The nomination of candidates shall take place at the meeting of the Council in June.

5. Duly nominated candidates will be required to present themselves for examination in chemistry and physics, Part I. of the pre medical examination of the Conjoint Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England held in July.

[illegible] the [illegible] shall [illegible] papers [illegible] the [illegible] addition to being marked in the ordinar[illegible] pre-medical examination.

7. The result of the examination [illegible] the Council, and the scholarship s[illegible] candidate who, having passed the highest number of marks.

8. Candidates must have obtained their instruction in chemistry and physics at an institution adequately equipped for instruction in those subjects.

9. A scholarship shall be tenable for five years, but no longer.

10. The stipend shall be paid yearly or half-yearly, as may be determined, and the scholar shall receive the *first instalment* of his stipend within three months after his election to a scholarship.

11. Every scholar sha[illegible] to a medical school recognized by t[illegible]land, and to send to the secretary of [illegible]ession within three months after his [illegible]yearly to the secretary of the Royal [illegible]ificate from the dean of his medic[illegible] net has been satisfactory, and that he has been applying himself diligently to his studies; (c) to complete the pre medical examination of the Conjoint Examining Board in England within twelve months, and to pass the first professional examination (an[illegible] of the Board within three years from the date of [illegible]

[illegible] sable to supply such [illegible] which is accepted as sufficient by

Forms of petition and such information as is necessary for candidates for these scholarships may be obtained from the Secretary, Royal College c[illegible] Lincoln's Inn Fields, W.C.2.

[illegible] £100 per annum. [illegible] ining Board in [illegible] pre-medical examination, with synopses [illegible] examination in chemistry and physics, may be obtained from the Secretary, Examination Hall, Queen Square, W.C.1.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

AT a meeting of the Royal College of Surgeons in Ireland, held on November 15th, Mr. Andrew Fullerton, C.B., C.M.G., Professor of Surgery at Queen's University, Belfast, was unanimously re-elected President of the College, in room of the late Professor T. E. Gordon, Mr. Fullerton to hold office until June, 1930. At that date Mr. Atkinson Stoney, F.R.C.S.I., will have completed a second year in office as Vice-President and will become in due course President of the College.

UNIVERSITY OF BELFAST.

Correction.

IN the report of the meeting of Convocation of the Queen's University, Belfast, held for the purpose of electing eight members of the Senate (*Journal*, November 9th, p. 882), the name of one of the medical members elected was unfortunately printed as "J. S. Morrant." The correct name of the new member of the Senate is Dr. John S. Morrow.

Medical Notes in Parliament.

[From our Parliamentary Correspondent.]

The House of Commons this week read the Widows', Orphans', and Old Age Contributory Pensions Bill a third time, and sent it to the House of Lords. The second reading debate on the Unemployment Insurance Bill was begun.

The Parliamentary Medical Committee has arranged to visit, on November 28th, the Government lymph station at Hendon and the laboratories of the Medical Research Council at Mill Hill.

Mental Treatment Bill.

In the House of Lords, on November 19th, Earl Russell presented the Mental Treatment Bill, to amend the Lunacy Acts and for other purposes. He said the text of the bill would not be out for a day or two, and he did not propose to take the second reading until November 28th. He had been asked by Lord Sandhurst to say that the question which he had put down for November 20th would be withdrawn. The bill was read the first time.

Lord Sandhurst's question was to ask the Government if they would, in the present session, introduce legislation for the amendment of the lunacy law, as recommended by the Royal Commission on Lunacy and Mental Disorder in their report dated July, 1926.

National Health Insurance.

Provision of Additional Benefits.—Mr. Greenwood (Minister of Health) told Dr. Morris-Jones, on November 14th, that 5,883 societies and branches in England and Wales, comprising nearly 12,000,000 members, had made arrangements to provide ophthalmic treatment, including the provision of ophthalmic appliances, as an additional benefit. A further 1,156 societies and branches, with about 1,700,000 insured members, did not provide this benefit, generally because their surpluses had been used for other benefits. The number of approved societies contributing to the cost of dental treatment was 6,545, covering 12,727,000 insured members. Only 494 gave no dental benefit. Mr. Greenwood said that he was not in a position to make any statement about the funds of the approved societies, as affected by the Economy Act of 1926. He further stated that he was considering the question of altering the medical benefit regulations relating to gifts or inducements by chemists concerning national health insurance prescriptions.

Medical Benefit in Scotland.—Mr. Adamson, replying to a question on November 19th, said that the number of insured persons in Scotland entitled to medical benefit under the National Health Insurance Act was approximately 1,760,000. The number of doctors who had been removed from the medical lists of Insurance Committees in Scotland since the inception of medical benefit in 1913 was four. In each case removal had followed the prescribed inquiry.

Silicosis.

In reply to Mr. Hannon, on November 14th, Mr. Clynes enumerated the ascertained cases of silicosis during the last three or four years in the industries or processes covered by the Various Industries (Silicosis) Scheme. They were: one case each in sand-grinding (iron foundry), silica milling (silica flour manufacture), stone-crushing (road-making), tin mining, and lead mining; two cases in millstone dressing (corn milling); four cases in sand-blasting (metal works); ten cases in stonemasons' work; and 25 cases in coal mining. Mr. Clynes said these were mostly fatal cases, where the cause of death was ascertained by post-mortem examination, and must not be taken as a criterion of the incidence of the disease in the industries or processes concerned. The disease was not notifiable, and its diagnosis involved expert examination. Consequently, except in industries under the refractories industries scheme, where there were special arrangements for expert examination, the disease had not been diagnosed as silicosis, but as some other form of disease of the respiratory system. Extensive medical research and experience gained under the refractories industries scheme demonstrated that wherever workmen were exposed to silica dust they ran the risk of silicosis. The inquiry into the sandstone industry in 1928 showed 112 cases out of 454 workmen. In selecting industries and processes for inclusion in the Various Industries Scheme regard was had to the degree in which workers would be exposed to silica dust. Mr. Hannon asked that the Order should not be applied to any industry until the Home Secretary had the clearest evidence of the existence of the disease. Mr. Clynes said the greatest care was taken in the application of the Order.

On November 18th Mr. Short told Mr. Hopkin that the Home Secretary had received no complaint of any hardship caused by the statutory Rules and Orders under the silicosis schemes under the Workmen's Compensation Act, 1925, nor against the proviso that the scheme should not apply where the rock contained less than 50 per cent. of silica. If Mr. Hopkin had any evidence of such hardship the Home Secretary would be glad to consider it. The limit was inserted in the scheme for the purpose simply of excluding the granite industry, which was the subject of a special medical inquiry, and the question of its retention would come up when the report of that inquiry was available. In reply to a further question, Mr. Short informed Mr. Hopkin that no information or complaint had reached the Home Secretary that an increasing number of men in and around Cross Hands, Carmarthenshire, were suffering from anthracosis, nor that a number of men had died from this complaint. The Home Secretary had no evidence at present that the blackened condition of the lungs, described as anthracosis, was a cause of disablement. If Mr. Hopkin could furnish him with definite particulars of cases where this condition was stated to have caused death or disablement the Home Secretary would consider them in consultation with the Mines Department and make any necessary inquiry.

War Pensions.

On November 18th Mr. F. O. Roberts, replying to questions on war pensions, said that the operation of the seven years' time limit on the making of fresh claims for disablement, and of the arrangements made by the late Government for dealing with certain cases affected by it, had been investigated by him. At the present date, more than ten years since the men were demobilized, cases in which disablement by war service could now be justifiably claimed for the first time were few, and would become fewer. Old war wounds, thought to have been healed but now giving trouble for the first time since the war, were readily identifiable, and were already dealt with both by medical treatment and pensions. New claims in respect of some ailment or disease were more numerous, but comparatively few were found on investigation to be genuinely traceable to war service. For the future, the arrangements for dealing with belated claims for disablement would be such as to ensure the following essential points: (1) that no application was rejected solely on the ground that it was barred by the time limit; (2) that every applicant was given explicit opportunity to produce evidence in support of his claim; (3) that all evidence in support of a claim was fully considered and every reasonable line of investigation indicated by the claim was pursued to the full, including medical examination wherever necessary. It was important that ex-servicemen should feel assured that their claims were considered impartially. He was accordingly arranging to make use of the statutory powers of the local War Pensions Committees to hear and investigate cases of complaint from dissatisfied applicants. He intended, in addition, to secure the assistance of independent advice by the appointment of medical experts (to be nominated by the Presidents of the Colleges of Physicians and Surgeons), who would be associated with the department in advising on all cases in which there was material conflict of evidence on the claim.

Dr. Vernon Davies asked if Mr. Roberts's reference to medical experts applied to London headquarters alone, or would the provinces be included. Mr. Roberts: They will deal with all cases that are submitted.

Anthrax.—On November 18th Mr. Clynes told Mr. Dukes that 35 cases of anthrax had been reported this year in factories and workshops. Three of these cases were fatal. Cases were reported from Dewsbury, Earlsheaton, [illegible] Kidderminster, Liverpool, Kilmarnock [illegible] Stockport, Warrington, Runcorn, Bermon[illegible] [illegible] (Wilts), Worcester, Somerset, and Leeds [illegible] occurred among dock labourers, two of which were fatal. These were reported from Millwall Dock, London Dock, and Alexandra Dock, Liverpool.

Small-pox at Aden.—On November 18th Mr. Wedgewood Benn, replying to Mr. Knight, said he had seen a report by the Public Health Commissioner with the Government of India on the outbreak of small-pox at Aden, which assumed menacing proportions last March. In view of the serious situation with which the authorities were faced, mainly through concealment of cases, he would not feel justified in questioning the measures they found necessary to deal with it. Mr. Knight's question impugned the siting and the adequacy of the contagious diseases hospital.

Deaths from Diphtheria, Cancer, Enteric Fever, and Small-pox.—Miss Lawrence, in reply to a question by Mr. Bromley on November 18th, stated that, for the first quarter of this year, there were 1,113 deaths registered in Great Britain from diphtheria, 14,376 from cancer, 75 from enteric fever (including paratyphoid fever), and 8 from small-pox. In the second quarter of 1929 the figures were: diphtheria, 696; cancer, 13,968; enteric fever, 55; small-pox, 24. In the third quarter there were 568 deaths from diphtheria. The figures in regard to cancer were not yet available. There were 97 deaths from enteric fever, and 4 from small-pox.

Rheumatic Disease.—Replying, on November 14th, to Mr. G. White, who asked what the Minister of Health was doing to combat rheumatism, Mr. Greenwood referred to the report of the chief medical officer of health for 1928, passages of which report upon treatment for acute rheumatic disease. Mr. Greenwood added that, as regards chronic rheumatic disease, the Medical Research Council was in touch with his department, and he was prepared to give sympathetic consideration to any practical proposals for treatment submitted by local authorities.

Deaths from Plague in British India.—Replying to Major Graham Pole, on November 14th, Mr. Greenwood said he had no reliable statistics of plague cases in British India during the last five years, but there was on the whole a marked decline. The deaths from plague in British India were: 361,843 in 1924, 117,717 in 1925, 196,249 in 1926, 32,160 in 1927, and 82,678 in 1928. Research work on prophylactic methods had yielded valuable results, but he was advised that there was not yet any reliable treatment for the disease.

Classification of Graded Milk.—Miss Lawrence told Mr. Kedward, on November 18th, that the Minister of Health was aware of the criticism against the present classification of graded milk and the lack of agreement among producers. Legislation would be necessary before any alterations could be made, and time would not permit of a bill this session.

Training and Employment of Midwives.—In reply to Viscount Elmley, on November 14th, Mr. Greenwood said the recommendations of the Departmental Committee on the Training and Employment of Midwives were under consideration. He could not state what action would be taken. Asked by Dr. Fremantle for a statement before the introduction of a private member's bill on the subject on December 6th, Mr. Greenwood said he would be glad to make a statement if possible.

Payment of Midwives' Fees.—In a reply to Mr. Remer, on November 15th, Mr. Greenwood said he was not aware of an increase in the number of cases where midwives had complained of difficulty in obtaining payment of their fees. He had no power to issue an Order that where maternity benefit was payable the midwife's fee should be paid to her direct. He was giving careful consideration to the whole question of the provision of midwifery services, particularly in relation to the arrangements for maternity benefit under the national health insurance scheme.

Epizootic Disease of Animals.—Mr. Buxton, in a reply on November 18th, said that epizootic abortion differed from scheduled diseases of animals in that it might persist in a herd from three to seven years, or even longer. If it were made notifiable, and the movement of animals was controlled, stock farming would be difficult and the cost of administering the Order enormous. Research work on this subject was being conducted all over the world, and the Ministry encouraged research workers in this country to concentrate on a cheap means of immunization.

Highlands and Islands Medical Service.—In committee of the House of Commons, on November 18th, Mr. Adamson moved the Highlands and Islands (Medical Service) Additional Grant (Money) resolution. This resolution provides that, for improving the medical service in the Highlands and Islands of Scotland, there may, on the passage of an Act, be paid to the Medical Service Fund, in addition to the £42,000 already payable, such sums as may be voted by Parliament for the purpose. Mr. Adamson announced that a debate on the resolution would take place at a later stage. Dr. Elliot concurred in this course, and the resolution was agreed to. On November 19th the resolution was reported, and Mr. Adamson introduced a bill based on it. This was read a first time.

Symptoms of Nervous Disease subsequent to Vaccination.—On November 19th Mr. Greenwood, replying to Mr. Groves, said 34 cases had been brought to the notice of his department as having occurred in the ten months ended October 31st, and as being cases with symptoms suggestive of disease of the central nervous system, following within a month of vaccination. Of these, 18 were fatal. All cases of this character were reported to the Committee on Vaccination. He could not say how many of the 34 cases were regarded by the committee as cases of encephalitis following vaccination.

Washington Hours Convention.—On November 19th Miss Bondfield told Mr. Mander that the Government was preparing legislation in respect of the Washington Hours Convention, but awaited certain changes of legislation in Northern Ireland which were required before ratification of the Sickness Insurance Conventions could be effected. Among the draft conventions still under consideration were those dealing with maternity, white lead, weekly rest (industry), workmen's compensation (accidents), and night work in bakeries.

Exposure of Foods for Sale.—Mr. Greenwood, on November 19th, told Mr. Mander that he was aware that the conditions under which bread and other foods were exposed for sale sometimes left a good deal to be desired. Some of the grounds of criticism could be removed by action of the competent local authorities under Section 72 of the Public Health Act, 1925. What was really needed was the creation of sounder public opinion in such matters, which would continue to receive his attention.

Proposed Colony for Mental Defectives.—Miss Lawrence, replying to Mr. Blindell on November 19th, said that the Minister of Health was informed that the Lincolnshire Joint Board had not yet succeeded in acquiring a property for the development of a colony for mental defectives; but a conference between the Joint Board and the Board of Control on this subject would take place on November 28th.

Notes in Brief.

All the 146 local authorities under the Blind Persons Act have arranged to promote the welfare of the blind.

The Cabinet Committee engaged in a survey of social insurance schemes is also to consider the question of raising the present limit of £250 entitling participation in the National Health Insurance Act to a figure more related to the existing cost of living.

There is a possibility that foot-and-mouth disease may be transmitted by the use, as containers for feeding stuffs, of bags made from hessian wrappers in which meat has previously been conveyed from South America. The Ministry of Agriculture is consulting with firms in the South American meat trade about the adoption of a wrapping which cannot subsequently be so used.

In consultation with the Minister of Agriculture, Mr. Greenwood will consider the suggestion of fixing a *maximum* water content for bread.

Mr. Lansbury proposes to permit mixed bathing in the Serpentine next summer, but does not at present contemplate making any special arrangements for sun-bathing.

The Secretary for Scotland is considering whether or not it is desirable that the decisions of local authorities on proposals to establish offensive trades in new premises should be final.

The Minister of Health is advised that there is no evidence of danger to the health of the community from the importation of second-hand clothing into this country to justify the imposition of restrictions to stop this import.

Medical News.

An evening reception will be held by the Royal Society of Medicine at 1, Wimpole Street, W.1, on Monday, December 16th. The President and Lady Dawson of Penn will receive Fellows and their friends at 8.30 p.m., and Commander L. C. Bernacchi, O.B.E., will give an illustrated address on Southern Polar exploration. Admission will be by ticket only, to be obtained from the secretary.

The eighty-second half-yearly dinner of the Aberdeen University Club, London, will be held at the Trocadero Restaurant on Thursday, November 28th, under the chairmanship of Dr. T. Wardrop Griffith. Further information may be obtained from the secretary, 9, Addison Gardens, W.14.

The tenth annual dinner of the medical officers of No. 14 Stationary Hospital will be held at the Trocadero Restaurant, Piccadilly, on Friday, December 6th, at 7.45 p.m. Colonel C. R. Evans, D.S.O., will be in the chair. Any member of the mess wishing to attend, and who has not received a notice, is asked to apply to the secretary, Dr. H. L. Tidy, 39, Devonshire Place, W.1.

The Medico-Legal Society will hold its annual dinner on the evening of Friday, December 13th, at the Holborn Restaurant, with the president, Lord Riddell, in the chair.

The 150th anniversary of the Birmingham General Hospital will be commemorated by a dinner at the Grand Hotel, Birmingham, on the evening of Tuesday, December 10th.

A Chadwick Lecture on public health law and administration introduced by the Local Government Act, 1929, will be delivered by Mr. William A. Robson, Ph.D., barrister-at-law, in the Inner Temple Hall on Tuesday, December 3rd. The chair will be taken by Sir William J. Collins, M.D., at 8.15 p.m. Admission to the lecture is free.

At a joint meeting of the Sections of Psychiatry and Disease in Children of the Royal Society of Medicine on Tuesday, December 10th, at 8.30 p.m., there will be a discussion on "The difficult child," in which members of the Child Guidance Council will also take part.

The Lloyd Roberts Lecture will be delivered at St. Mary's Hospital, Whitworth Street West, Manchester, by Mr. Comyns Berkeley, M.D., M.Chir., on Wednesday, November 27th, at 4.15 p.m.: the subject is "The teaching of midwifery."

of

on Wednesday, Thursday, and Friday, December [illegible] and 6th. The opening ceremony will be performed on December 4th, at 2.30 p.m., by the Right Hon. Arthur Greenwood, M.P., Minister of Health. The annual dinner of the Institute will be held on the evening of December 6th at the Trocadero Restaurant.

The forty-first Congress [illegible] the Royal Sanitary Institute will, at [illegible] Council, be held at Margate from Ju[illegible]

St. Andrew's Hospital, Dollis Hill, will celebrate its Patronal Feast on Sunday, December 1st, from 3 to 6 p.m. His Eminence Cardinal Bourne, Archbishop of Westminster, will distribute certificates of training and pay a visit to the new ward pavilion.

The Fellowship of Medicine announces that the following three lectures will be given at the Medical Society's lecture room, 11, Chandos Street, Cavendish Square. On Monday, November 25th, at 5 p.m., Mr. T. G. Stevens will lecture on prolapse (no fee to medical practitioners); on Tuesday, November 26th, at 8.30 p.m., Dr. Kinnier Wilson will speak on encephalitis—its varieties and relation to fevers and exanthems; and on Friday, November 29th, at 8.30 p.m., Dr. Kinnier Wilson will discuss the disorders of movement, including their classification and pathogenesis. On November 25th, at 10 a.m., Mr. Denham Pinnock will give a special demonstration at the Victoria Hospital for Children, and on November 28th, at 4.30 p.m., Dr. Thomas Marlin will give a demonstration of spinal manipulation at the Hampstead General Hospital, Haverstock Hill; both demonstrations are free to medical practitioners. At St. Mark's Hospital there will be an all-day course from November 25th to 30th. Three special courses will begin on December 2nd and will continue for two weeks; these are an afternoon course at the Infants Hospital, an afternoon course in dermatology at the Blackfriars Hospital for Skin Diseases, and a general practitioners' course at the London Temperance Hospital daily from 4.30 to 5.45 p.m. Detailed syllabuses of all these courses, the advance list of special courses for 1930, and particulars of the general course, may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE biennial Huxley Lecture will be given by Sir William Bragg, D.Sc., F.R.S., in the Lecture Theatre of Charing Cross Hospital Medical School, Chandos Street, W.C., on Thursday next, November 28th, at 3 p.m. The title of the lecture is "The crystal structure of organic substances in its relation to medicine."

SIR LESLIE ORME WILSON, late Governor of Bombay, will speak on "The Hospital for Tropical Diseases in London and its work for the Empire" at a meeting at 44, Lancaster Gate, W., on November 28th, at 5 p.m. Admission is by invitation cards only, which may be obtained from the resident secretary, Hospital for Tropical Diseases, Endsleigh Gardens, W.C.1.

A SPECIAL course in infants' diseases for medical officers of welfare centres and others interested will be held at the Infants Hospital, Vincent Square, Westminster, from December 2nd to 15th, under the auspices of the Fellowship of Medicine. In addition to lectures on different subjects, and lecture-demonstrations with clinical illustrations, visits will be paid to a pasteurizing plant, a nursery training school, and a venereal diseases centre. This last visit will be paid in the morning, but otherwise the course is held during the afternoons. The fee for the course is three guineas, and the number is limited to fifteen. Applications should be sent to the secretary of the Fellowship, 1, Wimpole Street, W.1, from whom further details may be obtained.

THE medical profession of Bury St. Edmunds held their annual armistice dinner on Saturday, November 16th, when the total number of guests was forty. Among the guests were Dr. Alfred Cox, Medical Secretary of the British Medical Association, Sir Thomas Horder, Bt., and others from London, Ipswich, Norwich, and Cambridge. This is the tenth year in which the dinner has taken place, and the attendance was larger than ever before.

THE Duchess of York laid the foundation stone of the new general hospital at Southend-on-Sea on November 12th. The lay-out of the site provides for a hospital with over four hundred beds. The ground, which comprises over twelve acres, has been given, with a contribution of £20,000, by Lord Iveagh, who has also generously promised to give £1 for every £3 subscribed by the public to the hospital fund during 1929. The first section, which it is hoped to complete in about two years, will provide 196 beds, an administrative block, two ward pavilions, a children's wing, an operating electrical block, and a nurses' home. Alderman H. A. Dowsett, chairman of the new hospital fund, stated that the present contract amounted to £130,000, of which £35,000 had been promised. He acknowledged the generosity of Lord Iveagh and also a munificent gift of £58,000 by Alderman A. Martin, which formed the nucleus of an endowment fund.

A NEW film showing the work of the Papworth Village Settlement was exhibited to the press on November 14th at 89, Wardour Street. In the film, which was made under the auspices of the Central Council for Health Education, health propaganda is successfully woven into the texture of a romantic story. Societies engaged in health propaganda are invited to apply for particulars about the exhibition of the film, to the secretary, Papworth Village Settlement, 10, Upper Woburn Place, London, W.C.1.

DR. JOHN CLARKE has been elected chairman of the Rotherham Insurance Committee.

AT a meeting of the executive committee of the International Union against Tuberculosis in June, it was decided that the following three subjects should be discussed at the next international conference, which will be held in Oslo from August 13th to 16th, 1930: B.C.G. vaccination against tuberculosis; thoracoplasty in the treatment of pulmonary tuberculosis; and instruction in tuberculosis for undergraduates. During a discussion on the Vernes flocculation test for the diagnosis of tuberculosis the view was expressed by Dr. Derscheid of Belgium that there seemed to be no justification for introducing this method in the normal work of dispensaries.

WE have received the first issue of *Boletin de la Sociedad Cubana de Dermatologia y Sifilografia*, [illegible] department for diseases of the skin an[illegible] The journal, which is issued bimonthly, of Dr. Alberto Oteiza y Setien, contains original articles, with English summaries, abstracts from current literature, and society intelligence.

THE University of Paris has conferred the degree of doctor *honoris causa* on Dr. Roux, professor of clinical surgery in the University of Lausanne.

THE seventh annual congress known as *Journées Franco-Belges* will be held in Paris from December 4th to 9th. Further information can be obtained from the general secretary, M. Sapet, 5, Rue Garancière, Paris.

PROFESSOR ARZT has been elected dean of the medical faculty of Vienna for the third time, and Professor Euler has been elected dean of the medical faculty of Breslau.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TRANSIENT ATTACKS OF OEDEMA.

DR. W. H. LOWMAN (Coventry) writes: Could any practitioner suggest diagnosis and treatment for the following case: A child, aged 3, becomes restless, and oedema develops without redness on the forehead and eyes; there is slight pyrexia, but 100.5° is the highest temperature I have found at the morning visits. In a few days the oedema of face subsides, and a similar condition appears in both arms and hands, suggesting the oedema of nephritis, though there is not a trace of albumin in the urine. When this disappears, in about a week, the legs similarly become affected with the swelling, which has not yet entirely subsided elsewhere, though it is improving. To-day, although the hands have been normal for nearly a fortnight, they have become swollen again, though at present the arms are not affected. There is peeling of the skin after subsidence of the swelling for the second time. The condition has lasted now a month; the child takes food fairly, but is restless and sleepless.

SENSATION OF ASPHYXIA DUE TO ETHYL CHLORIDE INHALATION.

DR. W. E. H. QUENNELL (Shenfield), in answer to "W. D." (November 16th, p. 928), writes: A possible explanation for the feeling of suffocation experienced during the induction period with ethyl chloride lies in the fact that it is being given in too concentrated a vapour. Whatever method is employed, whether a Clover inhaler, an open mask, or ethyl chloride bag, the success, in my opinion, lies in commencing with a small dose and gradually increasing the amount. I usually begin with 0.5 c.cm. and add 0.5 c.cm. every ten seconds, complete anaesthesia being produced in about one to one and a half minutes; I require, on an average 3 to 5 c.cm. in all, depending on the patient. I use ethyl chloride flavoured with 1/2 per cent. eau de cologne, which completely masks the unpleasant smell; this preparation (thilocologne) is obtainable from W. Bredt, 41, Great Tower Street, E.C.4.

DR. H. S. BURNELL-JONES (London, N.W.5) writes: Unconsciousness can be easily produced with ethyl chloride by giving it upon an open mask; this method causes no feeling of suffocation. A piece of lint is equally effective, especially for the extraction of one or two teeth in small children when there is no anaesthetist available. I write from experience, both as patient and anaesthetist.

ABDOMINAL SURGERY AT SEA.

DR. GORDON MILNE, ship surgeon, P.&O.S.N.Co., writes: With reference to the inquiry of "T. S. S." (September 28th, p. 604), he will find *Surgical Emergencies*, by Russell Howard, published by Edward Arnold and Co., a tower of strength to him in emergency surgery of the abdomen or any other part of the human body. In addition, I should suggest that he remember the three cardinal points of a good surgeon—a good light, a sharp knife, and tons of common sense.

FLEAS.

"J. L. M.," with reference to the inquiry as to a prophylactic against fleas, made by a correspondent on p. 744 and answered on pp. 793 and 838, draws attention to the use of essence of thyme recommended in the *Journal* of November 12th, 1921 (p. 818).

INCOME TAX.

Depreciation of X-Ray Apparatus.

"RADIO" refers to an answer in our issue of June 8th last (p. 1066), and inquires whether we can mention other cases in which depreciation has been allowed on *x*-ray apparatus at 10 per cent.

*** We are not in a position to give "Radio" any useful reference on this point—for one thing, we should not normally hear of the cases where the 10 per cent. allowance is given, and, for another, reference to individual cases or even areas is open to objection. We are, at least, not aware of a case where 10 per cent. has been refused after protest. "Radio" might point out that, even apart from any question of obsolescence, the depreciation through wear and tear of any machine or apparatus depends largely on its delicacy and the thermal and other strains to which it is subjected. On any ground an *x*-ray apparatus clearly has a shorter life than fixed heavy electrical plant, which receives an allowance at 7½ per cent. The fact that when the apparatus becomes obsolete and is renewed a special claim can be made should not be allowed adversely to affect the depreciation allowance. "Radio" may leave the practice before the obsolescence allowance can operate.

Expenses of Removal.

"R. W. B." was in the employment of the Ministry of Pensions to March 31st, 1927, and was disengaged until February 1st, 1928, when he was appointed M.O.H. to an authority some distance away. Can he claim as a deduction in arriving at his taxable income the expense of removing from one town to another?

*** No. Such an expense is not incurred in carrying out his duties, but as a preliminary in order to place him in the position to commence his duties. It is, of course, otherwise as regards the necessary expense of travelling about in the area for which he is responsible in order to do his work. On the facts "R. W. B.'s" outlay was in order to obtain the appointment, and was in the nature, therefore, of capital expenditure.

Motor and House Service Expenses.

"D. R.'s" original car cost £195, and was sold in April, 1928, for £115, when a similar new car was bought for £185. In March, 1929, the second car was sold for £120 and a superior type bought at the price of £247—a car similar to the one then sold would have cost £195. No depreciation has been allowed. What claims should be made? Two maids are kept at an estimated cost of £198; "D. R." claims half that sum as an appropriate deduction, but the inspector of taxes proposed to allow £66 only—that is, one-third. Which is correct?

*** As regards the cars, the first transaction involved no capital improvement, and "D. R." is entitled to treat as a professional expense of the year including April, 1928, the actual net expenditure—that is, £185–£115=£70. On the second occasion there was an improvement to the extent of £247–£195=£52, and "D. R." can claim only the actual outlay—that is, £247–£120=£127, as reduced by that sum; his net claim is, therefore, £127 *less* £52=£75. It is difficult to give any helpful advice on a question where so much depends on the actual conditions of the practice as it does where an allocation of the expense of the house and surgery service is concerned. If, from the domestic point of view, "D. R." and his family have, in effect, the assistance of one maid only, his claim is good, but if the employment of the second maid does assist, directly or indirectly, to put the domestic convenience on a level above a one-maid basis it is almost impossible to press his claim further. As regards the adjustment for private use of car, we agree that the relative mileage gives a correct basis of computation.

LETTERS, NOTES, ETC.

THE RACIAL INCIDENCE OF DISEASE.

DR. M. SOURASKY (London, W.1) writes: Dr. J. S. Mackintosh, in his letter in the *Journal* of November 9th (p. 877), in reply to my insistence o[n] a series of further [r]esearch[es] oretical. These, hov[ever] kintosh made the [s]tatement prone to tonsils and [adenoids] be has consists of [the] reasons derived fro[m] these theoretical considerations in [support] problems of the racial origin of Jews, and the climate in which the race originally developed, but also the racial nature of the people of this country and the climates to which the different components have at different times been subjected. All this is interesting, but proves little.

MOTORIST'S HEEL.

"G. F. P." writes: In his article on "motorist's heel" in your columns of November 9th (p. 855) Mr. A. P. Bertwistle has evidently overlooked my note on the subject on May 25th (p. 979), which suggested that the condition complained of by "Giza's" patient (May 11th, p. 890) may have been caused by "constriction of the circulation of the foot resulting from undue flexion of the ankle while operating the accelerator pedal in driving a car." I wrote this note because I had observed the condition as a personal experience during a 600-mile journey to Scotland; it recurred while doing short local journeys. The absence of relief after a night's rest was a puzzling feature. The discomfort was lessened by raising the heel of the right foot by means of a wooden block screwed to the floor boards. I suggested, too, in my note that the wearing of boots, especially if rather tightly laced, is a predisposing cause. There seems to be proof of this in my own case, because I repeated the journey to the North of Scotland last September wearing shoes and felt not a trace of discomfort.

HERPES ZOSTER AND VARICELLA.

DR. HERBERT E. MARSDEN (Ormskirk) writes: A girl, aged 16, was admitted to hospital on October 9th last suffering from scarlet fever. On October 22nd she developed herpes zoster. Two patients, convalescent from scarlet fever, one aged 5 and the other aged 7, who were in beds on either side of her, developed varicella on November 4th and 8th respectively.

PHYSICAL HYGIENE IN THE PREVENTION OF MATERNAL MORTALITY.

DR. H. S. HOLLIS (Hové) writes: During the last thirty years the fashion has much increased of women spending the last two months of [pregnancy] fire when not in bed. Surely this i[s] is of normal labour at the present tim[e] to infection during the puerperium. What chance would an athlete have of winning a contest, or a patient of regaining fitness after an acute disease or a major operation, if this form of training were adopted? I have noticed that those few patients who have a reasonable amount of exercise and fresh air up to the last have, in normal cases, confinements just as uneventful as formerly.

SLEEP IN HOSPITALS.

THE SECRETARY of the London Fever Hospital (Liverpool Road, N.1) writes: Adverting to the article in your issue of November 2nd (p. 816) under the heading of "Sleep in hospitals," may I be permitted to point out that the custom of not calling any patient before 7 a.m. has now been adopted in this hospital? For many years past it has been the practice for those occupying private rooms not to be awakened before this hour, and this practice l[ed] all patients, with satisfactory results. hours of duty for the nursing staff have s innovation.

DISCLAIMER.

DR. P. H. J. TURTON (Heanor) writes to disclaim any responsibility for a paragraph about himself which appeared in a local newspaper.

INFLAMMABLE THROAT LOZENGES.

DR. J. PEREIRA GRAY (Exeter) writes: A policeman on cycle patrol duty felt a slight sore throat. He bought some chlorate of potash lozenges and put them in his trousers pocket, which contained a box of safety matches. After cycling for a few minutes he thought he heard a slight explosion; a minute later he saw flames issuing, which burnt a large hole in his pants and trousers, caught his coat and waistcoat, and scorched his skin in several places. He managed to extinguish the flames, and, on investigating their cause, he noticed that the live heads of his matches were now dead and his lozenges had disappeared. This episode shows that if potassium chlorate lozenges and safety matches are carried about they should not be placed in the same pocket.

*** The danger is not so much from the match heads as from the red phosphorus on the box, as anyone can prove by gently rubbing a chlorate of potash lozenge along the side of an empty safety matchbox. We note that the cardboard packets containing chlorate of potash tablets sold to the public by Boots Pure Drug Co., Ltd., are labelled as follows:

CAUTION.

Tablets of Chlorate of Potash should not be carried loose in the pocket. They are liable to ignite if subjected to friction or heat. Before pressing, ironing, drying, or airing clothes in front of the fire, the tablets should be removed from the pockets of the garments.

SPECIAL WARNING.

Keep the Tablets away from matches.

"H. B." (London, N.W.) writes to say that he would be pleased to give to another doctor, or a doctor's son, his collection of fossils and shells.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 50, 51, 52, 53, 56, 57, and 58 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 235.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

458. Relapses during Liver Treatment in Pernicious Anaemia.

R. ISAACS (*Amer. Journ. Med. Sci.*, October, 1929, p. 500) states that in pernicious anaemia some symptoms of a relapse may occur during liver treatment. Periodicity is an outstanding feature of the disease, and is present also in the relapses. Eighty pernicious anaemia patients have been studied, and a record of 304 relapses compiled; of these, 166 occurred in the same season as a previous relapse in the same patient. A patient may therefore expect a relapse, or symptoms of it, more frequently in the same group of months as previous relapses have occurred, rather than at a new time of the year. The incidence of onset or relapse appears about equally distributed through the year. Many of these symptoms of a relapse appear in patients in whom the blood count remains normal. The following types illustrate certain forms of relapses, with and without anaemia: periodic symptomatic relapses with blood relapse; periodic symptomatic relapses without a concomitant change in the blood picture, (1) when the blood is normal, (2) accentuation of symptoms of relapse or the appearance of new symptoms when the blood count is practically stationary but at a low level, and (3) symptomatic relapses during a period of relative polycythaemia. Abortive relapses are indicated by loss of appetite, exacerbation of symptoms, or the appearance of new symptoms when the blood is normal or shows no corresponding change. Liver therapy is often discontinued because of the loss of appetite (gastro-intestinal or nervous relapse), and a haemopoietic relapse follows. If liver treatment be maintained the abortive relapse may pass into a remission. Relapses may occur in one or more systems (blood, gastro-intestinal, nervous, bone-joint, or muscular) without a corresponding involvement of other systems.

459. Tracheotomy and Tuberculosis.

J. D. ROLLESTON (*Brit. Journ. Child. Dis.*, July-September, 1929, p. 200) alludes to Landouzy's assertion that children who have undergone tracheotomy for laryngeal diphtheria are specially susceptible to tuberculosis and very few reach adult life. This assertion, which was based on the rarity with which Landouzy had found tracheotomy scars among recruits, met with considerable opposition from subsequent writers, particularly in Germany, Holland, Finland, and France, though some were inclined to regard it as responsible for chronic tonsillitis and respiratory infections. Rolleston records an example of tracheotomy for laryngeal diphtheria in mother and child, the former having been operated on in 1896 and the latter in 1928. Since her tracheotomy in 1896 the mother had enjoyed good health and had not had any respiratory disease, except during the influenza epidemic of 1918, when she lost her voice for two months. Rolleston had also seen several other adults who had undergone tracheotomy in childhood for laryngeal diphtheria but had not developed any obvious signs of tuberculosis subsequently, so that his experience agrees with that of Landouzy's opponents. In conclusion he suggests that in British fever hospitals—in most of which, contrary to the practice of many foreign clinics, tracheotomy is still the favourite operation and intubation the exception—medical officers might choose the future of tracheotomy cases as a subject for a thesis.

460. Alcoholic Pseudo-pellagra.

E. R. MALONEY and L. TULIPAN (*New York State Journ. of Med.*, September 1st, 1929, p. 1063) record their observations on 21 patients admitted to the dermatological clinic of the New York University medical school between June and October, 1928, with pseudo-pellagra due to alcohol; 20 were men and one was a woman. Their ages ranged from 24 to 67, the average age being 45. All had been addicted to the excessive use of alcohol in the form of cheap, green, unmatured synthetic liquor; often it was simply denatured raw alcohol. While drinking this they ate little or nothing, and during the warm months slept out of doors during the night exposed to the action of ligh
of raw green whisky rendered the
and thus caused the eruption usu
varied in appearance from slight redness, pigmentation, and wrinkling of the skin to a violaceous erythema on a dark pigmented base covered by scales or bullae on eroded areas and crusts where previous bullae had ruptured. When the lesions began to subside, large sheets of desquamation were observed in most cases. All but two patients, who died from delirium tremens, recovered rapidly without any special diet as soon as the alcohol was withdrawn. Although alcohol is a predisposing factor in true pellagra, the authors regard the cases as pseudo-pellagra for the following reasons. The patients did not present the mental and nervous symptoms of pellagra, and did not suffer from severe diarrhoea. The eruption in most cases was limited to the hands, only occasionally involving the face, and then only to a slight extent; it never affected the feet.

461. Immunization against Relapsing Fever.

W. M. ARISTOWSKY and [illegible] (*Zeit. f. Immunitäts u. exper. Ther.* [illegible] ave previously reported the [illegible] th cultures of relapsing feve [illegible] to 60° C. By this method [illegible] immunity, as evidenced by the appearance of spirochaetolysins in the blood, and by the resistance of the vaccinated subject to experimental inoculation with living spirochaetes. This immunity was, however, confined to the strain from which the vaccine was prepared, and did not extend even to the relapse races of the same strain of spirochaete. An attempt to vaccinate persons against the relapse races by a heat-killed vaccine met with failure, apparently owing to the heat-lability of the antigenic properties of these races. In their present communication the authors report results obtained by using old cultures in which the organisms have undergone degeneration. Cultures that had been incubated for three days and then kept at room temperature for two to three weeks were found to be avirulent and suitable for vaccination. Experiments made on a limited number of human beings showed that by means of these vaccines it was possible to produce immunity, either to the original strain or to a relapse race of the same strain. By combining the vaccines immunity was produced simultaneously, both to the original strain and to its first relapse race. Spirochaetolysins appeared in the blood, and were demonstrable for at least one and a half months after vaccination. There appears to be little doubt that the organisms in the old cultures used for vaccination were dead, so that the resulting immunity was not strictly of the type of an infection immunity.

Surgery.

462. Fractures at the Ankle.

F. J. COTTON and R. BERG (*New England Journ. of Med.*, October 17th, 1929, p. 753) consider that classification of the major ankle injuries, not as fractures but as dislocations complicated by fractures, gives a much simpler basis for treatment than do the various classifications founded on the mechanism of production or on anatomico-pathological details. Since, in nearly every case, efficient correction of the displacement (disregarding the bone lesion) is all that is necessary for the best possible results, the following classification is suggested: (1) outward dislocation, or Pott's fracture; (2) inward dislocation, or reversed Pott's fracture; (3) backward dislocation, or Cotton's fracture; and (4) upward luxation, a somewhat neglected though important class of major injury, which the authors discuss in detail. A plaster cast should be applied in any of the first three classes until union is solid, usually for six weeks in classes 1 and 2, and for seven to ten weeks in class 3. Further treatment with strapping and a built-up Thomas heel should then be applied. Cases in classes 1 and 2 should be practically normal in three months, but those in class 3 usually require three or four weeks longer. In order to avoid muscle atrophy
of the foot, early or late exercises
n class 4 cases is a compression
the tibia, with the fibula generally
remaining intact. It is a comminuted, semi-impacted type of fracture, rarely complicated by fracture of the os calcis, more rarely by that of the astragalus, and is not often compound. The diagnosis, which is confirmed by x-ray pictures, is often made without these by the abnormally high level of the internal malleolus in relation to the external one. This class of fracture requires more time to secure a weight-bearing joint than [illegible] needs not be expected to [illegible] by fixation [illegible] results. Th [illegible] reshaping

holding the foot down by traction with a Sinclair skate, a boot, or by skeletal traction with tongs attached to the os calcis. Open operation is justifiable and sometimes wise. Early fixation is followed by an ambulatory brace after union is firm. Minor injuries, such as strains, with or without ligament damage, tears of the ligaments, and fractures of the fibula at a higher level, should receive the same treatment as class 1 cases. In diastasis, careful inspection of radiograms shows a widening of the mortise. Various operations have been devised for this condition; but in fresh cases the deformity can be reduced by downward traction on the foot, combined with compression about the malleoli, the foot being held in the varus position.

463. A Radical Cure for Hydrocele.

B. L. SHARMA (*Indian Med. Gazette*, October, 1929, p. 571) describes a radical cure for hydrocele by means of quinine injections. Cases of hydrocele, varying in size and duration, have been successfully treated during the past two years by this method, and in no case has there been any re-accumulation of fluid. The method, which is said to be very simple, painless, and without any bad after-effects, takes only a few minutes to perform, so that patients can be sent home soon afterwards to resume their ordinary occupations. The requisites for the procedure are: a 10 c.cm. syringe with a needle 2½ inches long; a hydrocele trocar and cannula; and 10 c.cm. of a sterilized solution containing 20 grains of quinine bi-hydrochloride and 1 grain of salicylic acid. The scrotum is well cleansed and painted with tincture of iodine, while the patient is seated. The hydrocele is tapped with the trocar and cannula, the fluid thoroughly drained, and the cannula left *in situ*. The syringe is filled with the quinine and acid solution, which should be slightly warm, and this is introduced into the sac by inserting the needle into the cannula. The needle and cannula are removed, the puncture is rubbed well, and painted with tincture of benzoin. The patient should wear a suspensory bandage for some days. Owing to the slow absorption of the solution the scrotum remains larger than normal for about fifteen days, but without any pain or inconvenience; it then becomes reduced to its normal size.

464. Traumatic Subclavian Arterio-venous Aneurysm.

E. L. GILCHREST (*Arch. of Surg.*, September, 1929, p. 375) describes a case of subclavian arterio-venous aneurysm in a Mexican, aged 35, following a gunshot wound through the chest. The patient was able to follow his occupation as a bookkeeper although the right arm gradually increased in size and the veins in the axilla and over the anterior part of the chest became more and more distended. After seven years his arm was so large and heavy that it could not be used, and two ulcers had developed, one on the dorsum of the hand and the other on the flexor surface of the forearm. The man also suffered greatly from shortness of breath and there was a very large swelling on the right side of the chest, the shoulder girdle, and the entire right arm and hand, with marked distension of the veins concerned. A systolic thrill was palpable in the supraclavicular region, in the axillary region, and over the lower third of the inner aspect of the upper arm by the basilic vein. Diagnosis of an arterio-venous aneurysm was made on the great swelling of the arm and dilatation of the veins, the continuous purring thrill, a continuous buzzing accentuated during systole, the centrifugal transmission of the bruit and thrill along the axillary and basilic veins, the elevation of blood pressure on temporary deep pressure over the site of the lesion, on the increase of oxygen content in the veins of the right arm, the decrease in local temperature, and the enlargement of the heart. Before the operation the patient was kept in bed for several weeks with the arm elevated and with crêpe bandages on the arm and shoulder girdle; this gave rest to the heart and reduced the swelling. Operative treatment consisted in the proximal ligations of artery and veins, which improved the condition but did not effect a cure. Ten months later the patient returned, following the development of, and haemorrhage from, a varicose ulcer on the flexor surface of the right forearm; distant ligations completing the quadruple ligation cured the condition.

465. Appendicitis in Typhoid Fever.

S. G. GIARDINA (*Giorn. med. dell. Osp. civ. di Venezia*, August, 1929, p. 155), who records four illustrative cases, with three recoveries and one death after operation, gives the following statistics of the frequency of appendicular lesions in typhoid fever. Christian in 119 typhoid necropsies found considerable lesions of the appendix in 19; in 41 fatal cases of typhoid fever at St. George's Hospital H. D. Rolleston found that the appendix was normal in 26, swollen in 5, ulcerated in 8, and perforated in 2. As regards the frequency of perforation of the appendix in typhoid fever compared with typhoid perforations in general, Madelung found that in 949 cases of intestinal perforation the appendix was perforated 51 times, or in 5.3 per cent. Kelly also reported a frequency of 5 per cent., and Berard and Vignard of 11 per cent. In 167 cases of typhoid perforation Fitz found 5 with perforation of the appendix, while Waker found 15 among 134, and Osler 5 in 16. The age at which perforation of the appendix in typhoid fever is most likely to occur is from 17 to 25, and the stage of the disease the third or fourth week. The mortality among the cases operated on is about 75 per cent., which is somewhat higher than that for perforation of the intestine. The operation in each of Giardina's cases was performed under local anaesthesia; three patients recovered and one died two days after the operation. In three cases, one of which was fatal, the appendix was inflamed and oedematous but showed no ulceration; in the fourth case superficial ulcers were found.

Therapeutics.

466. A New Local Anaesthetic.

H. FLÖRCKEN and O. MUES (*Münch. med. Woch.*, October 11th, 1929, p. 1714) describe the uses as a local anaesthetic of a complicated derivative of the quinoline series, to which also belong a number of other useful medicinal products such as atophan and yatren. This substance, which is marketed under the name of "perkain," forms colourless crystals which are readily soluble in water with neutral reaction, and which, unlike cocaine, can be sterilized by boiling. It should be kept in alkali-free glass vessels, and to ensure this it is recommended to add a few drops of dilute hydrochloric acid to each litre of the solution. The local anaesthetic action of perkain is said to be far greater than that of cocaine—as much as 100 times greater when applied to the rabbit's cornea; perkain 1 in 1,000, acting for one second, has about the same effect as 1 in 1,000 cocaine acting for half a minute, as estimated by the acid stimulant effect on the nerve endings of the reflex frog; the drug is, however, about five times more poisonous than cocaine, and deaths are recorded from doses of 0.13 and 0.2 gram of the substance. It is chiefly recommended for its slow rate of elimination and more prolonged period of action, which may extend to several hours; the after-pain is said to be much less than after novocain. The maximum dose has not yet been determined, and it is advised that the drug should not be used in concentrations of over 0.5 to 1 per 1,000.

467. Bacteriophage Treatment of Cystitis.

J. A. VOSS (*Norsk Mag. f. Laegevid.*, August, 1929, p. 853) records his observations on *B. coli* cystitis and pyelitis by bacteriophage therapy. He states that the best place to find a good bacteriophage is in the contents of septic tanks. By employing filtrates from different tanks it is almost always possible to obtain complete lysis of the *B. coli* found in the urine. Among 100 cases of chronic cysto-pyelitis Voss found only five cases in which *B. coli* did not undergo complete lysis *in vitro*. Before the bact[illegible] treatment is begun the patient should be put on an [illegible] being forbidden and carbonates [illegible] is sufficiently alkaline, 1 c.cm. of the bacteriophage should be [illegible] and 10 c.cm. intravesically for three day[illegible] urine should be kept alkaline for the ne[illegible] cases which Voss has been able to keep under observation out of 59 treated, 16, or about 60 per cent., were successful. Almost all these 16 patients were chronic cases. The treatment is most likely to be successful in the pyelitis of pregnancy, and in children, whereas it is rarely efficacious in men.

468. Treatment of Epilepsy.

As the result of ten years' experience in treating very many cases, G. CARRIÈRE (*Bull. de l'Acad. de Méd.*, October 1st, 1929, p. 137) strongly advocates the use of a combination of potassium boro-tartrate and gardenal in the treatment of epilepsy and other nervous conditions; he claims to have achieved much better results thus than from the employment of these drugs separately or of bromides. Failures are ascribed to insufficient or diminished dosage, premature cessation of treatment, dietetic and hygienic errors, or physical or mental overwork. Owing to the many pathogenic factors of the disease, this form of therapy, while markedly beneficial in cases of epilepsy, should very often be combined with some specific treatment, such as opotherapy, treatments for visceral or functional disorders, etc. In loss of consciousness, vertigo, and in Jacksonian epilepsy due to intensive lesions, such as cerebral tumours, this treatment is not so successful. Other conditions in which Carrière has found the combined medication to be of benefit are: psychasthenia,

neurasthenia, the mental and nervous troubles of Parkinsonism, insomnia, post-traumatic delirium, the neuropathic excitement of exophthalmic goitre, angina pectoris, neurosympathetic functional syndromes, sympathicotonia, migraine, and essential or neuropathic palpitation. Certain infantile conditions have also been benefited by it; such are convulsions, spasmophilia, the tetany of nurslings, chorea, and involuntary nocturnal micturition. The treatment in slight or moderately severe cases should commence with a dosage of 1.5 grams of the tartrate and 0.15 gram of gardenal daily in three doses. In severe cases larger doses should be given, and these should be increased until one is reached which controls the crises. This treatment should be continued for three years after the last paroxysm; it may then be gradually and carefully diminished each month. The administration of 0.5 to 0.75 gram of each drug should be continued for many years.

Disease in Childhood.

469. Brain Tumours in Childhood.

DURING the last twenty years it has become more evident that neoplasms are not so rare in infancy and childhood as was formerly thought. Though the majority of these cases are considered absolutely malignant and inoperable, the recent advance in surgical technique has markedly increased the number of operative successes. In a study of 350 cases of verified brain tumours, F. H. LEAVITT (*Amer. Journ. Med. Sci.*, August, 1929, p. 229) found that the ratio of juvenile to adult cases in this series was 1 to 14, and he urges an earlier recognition of cerebral tumours in children with obscure head symptoms. A frequent site of juvenile brain tumours is the cerebellum, this being the location in 60 per cent. of the cases. There is a somewhat general symptomatology, including a history of rather rapid onset in which the child becomes suddenly ill with vomiting and headache. This stage is soon followed by drowsiness and signs of increasing intracranial pressure, as noted by a rapidly developing choked disc with retinal haemorrhages, disturbance of gait, enlargement of the head, and Macewen's "cracked-pot" sign in infantile cases, with the localizing symptoms of the growth determinable by careful neurological examination. The usual types of neoplasms encountered are tuberculomas, congenital tumours, and those of the glioma group. Statistics show a lessening frequency of tuberculous growths. The congenital tumours are generally suprasellar lesions and produce symptoms of dyspituitarism. The glioma group preponderate in childhood both as regards number and malignancy. They are the pre-adolescent tumours, and constitute about 75 per cent. of the neoplasms in pre-adolescent brains and 40 per cent. of all brain tumours. In childhood they usually occur in the mid-cerebellar region, arising from the roof of the fourth ventricle and projecting into the vermis. This is the most critical position as regards risk to life and the production of an early hydrocephalus by pressure on the iter. Ventriculography and encephalography are often valuable diagnostic procedures, but they necessitate great care owing to the dangers attending their use. Surgery and electrotherapy offer the best measures for cure and alleviation of distressing symptoms in these patients. In support of the "foetal-rest" theory of the genesis of neoplastic cerebral growths, Leavitt reports the identical occurrence of cerebral tumours in monozygotic twins.

470. Pyuria in Infants.

J. R. WILSON and O. M. SCHLOSS (*Amer. Journ. Dis. Child.*, August, 1929, p. 227) present a study of the post-mortem findings in forty-nine infants and young children under the age of 3 years whose urine contained pus during life and who were of the clinical type which is usually termed "acute pyelitis." In the milder forms the urine contained moderate amounts of pus during the course of some acute infection. The severer cases were represented by infants who were acutely ill with [illegible]ed pyuria. The most commo[illegible] inflammatory foci in the [illegible] In their earliest and simplest form the foci are small circumscribed areas of infiltration by small mononucleated and polymorphonuclear cells; they are often adjacent to small blood vessels. As the disease advances or becomes more severe, the lesions grow larger and contain more polymorphonuclear cells, until, in the severest forms, frank abscess formation is evident, presenting the typical picture of acute suppurative nephritis. The authors do not consider that pyuria in infants is always due to suppurative interstitial nephritis; it may be caused by other conditions, which, however, are relatively rare, such as congenital anomalies of the urinary tract, cystitis, and renal calculi. They incline to the view that the infection is blood-borne rather than an ascending one.

471. Paroxysmal Sneezing in Whooping-cough.

A. MONCRIEFF and R. C. LIGHTWOOD (*Arch. Dis. in Childhood*, August, 1929, p. 240) state that various equivalents of the whoop in pertussis have been described and that the occurrence of these equivalents seems to indicate a central nervous origin for the spasmodic phenomena of pertussis. These equivalents include paroxysmal sneezing, yawning, and attacks of hiccup. The true nature of these cases is often not recognized, so that they are liable to spread the disease. They record the case of a girl, aged 3 years and 11 months, who, after she had been whooping for two months, began to sneeze instead. The sneezing attacks occurred about ten times a day; after six weeks the whoop returned and she had both whooping and sneezing attacks. Bacteriological examination of the muco-pus discharged from the nose in one of the attacks showed the presence of pertussis organisms. The one other child in the family had an ordinary attack of whooping-cough after that of his sister.

472. Oral Administration of Insulin in Infantile Diabetes.

THE treatment of infantile diabetes in out-patients by means of insulin injections is fraught with difficulty, and oral administration is therefore desirable. Successful cases of its administration in this way are reported by M. OTTOW (*Münch. med. Woch.*, September 20th, 1929, p. 1584), who remarks that the effects appear slower than when insulin is injected, the disappearance of sugar from the urine preceding the return to normal of the blood sugar. The insulin was well tolerated. Ottow is inclined to admit the occurrence of a cumulative effect, leading to an increase of the sugar tolerance through regeneration of the still functionally active islets of Langerhans. He believes that such oral insulin therapy will play an important part in the treatment of infantile diabetes.

Obstetrics and Gynaecology.

473. Pudendal Anaesthesia in Midwifery.

M. GUTMAN and V. METZ (*Zentralbl. f. Gynäk.*, August 3rd, 1929, p. 1952) describe their experience of anaesthesia by injection of the pudendal nerve, as advocated by Müller and later improved by Sellheim. The aim is to block the nerve supply to the muscles of the pelvic floor and the skin of the perineum and labia. The injection is made into the nerve as it passes from the lesser sciatic foramen into the pelvis. The patient lies across the bed with thighs adducted and flexed; the injection is made on the medial surface of the ischial tuberosity, 5 cm. deep, and in an almost horizontal direction; 10 to 12 c.cm. are injected. The needle is then withdrawn for about 2 to 3 cm. of its length and passed downwards and laterally; the remainder of the solution is then injected, thus blocking the collaterals to the posterior cutaneous nerve of the thigh. About 20 c.cm. of a 1 per cent. solution of novocain and adrenaline are required for each side. The needle must not reach the lesser sciatic foramen for fear of damaging the great vessels. Anaesthesia is complete in ten to fifteen minutes, and lasts one and a half to two hours. The authors state that this method can only be useful when delivery is expected within two hours. To establish this as a certainty a rectal examination is made; if the head advances when the patient bears down, the injections can be given. They ease the patient greatly by relieving her of all pressure on the pelvic floor and of the pain due to the stretching of the soft parts; the treatment does not, however, affect the actual labour pains. The pelvic floor relaxes well, thus avoiding injury and subsequent disability. The authors do not find that perineal tears are diminished by this method, but episiotomy and perineal repairs are easy as the perineum is completely insensible. Only in complete tears extending to the rectum are some injections round the anal region needed, to anaesthetize those branches of the inferior haemorrhoidal which do not arise from the pudendal nerve. This method is said to be useful not only in spontaneous deliveries, but in low forceps and breech cases. In their 130 cases the authors have had only eight failures, which were probably due to faulty technique. The method is said to be simple and very suitable for general practice. No bad effects or accidents have occurred except a transient pallor of the face.

474. Pelvic Peritonitis after Curetting.

P. FRASSINETI (*Il Policlinico*, Sez. Chir., September 15th, 1929, p. 445) reports a case in which curetting for virginal septic endometritis from common vaginal bacteria was followed by apparently primary pelvic peritonitis. External sepsis due to faulty technique and lesions of the uterus being excluded, it would have been expected that curetting, instead of

removing an existing infection, would have helped to drive it through the lymphatics or blood vessels to the pelvis; this gives rise, as a rule, to pelvic abscess, or abscess of the broad ligament, or, very rarely, to pelvic peritonitis. The symptoms in the case reported led to the diagnosis of primary pelvic peritonitis. Frassinoti doubts if such a condition can develop through the blood vessels and lymphatics, since owing to anatomical conditions this cannot happen without an intermediate infection in the broad ligament. Faure and other writers admit that infection of the peritoneum through the blood vessels may give rise to phlebitis, abscesses, and visceral suppuration, but not to isolated pelvic peritonitis; infection through the lymphatics is almost impossible owing to anatomical considerations. Consequently the mucosa is the route of infection, as in the case of gonococcal and pyogenic invasions under favourable conditions, notwithstanding that the mucosa of the tubes, being more resistant, is not affected. The author thinks that this may be true in the absence of surgical operations. Infection through lymphatics excluded, curetting could not have caused primary pelvic peritonitis. Frassinoti suggests that Hegar's dilators, which fit closely to the cervix uteri, do not allow propulsive action to evacuate the septic contents of the uterine cavity; these, consequently, enter the Fallopian tubes and pass to the peritoneum. To avoid this, Frassinoti suggests a modification of Hegar's dilators. The cylinder is interrupted in its circumference by four narrow channels which, while allowing dilatation to be accomplished, leave an outlet for the escape of septic matter.

475. Etiology of Pregnancy Toxaemias.

R. L. LARSEN (*Amer. Journ. Obstet. and Gynecol.*, September, 1929, p. 374) discusses the etiology of the pregnancy toxaemias from the inductive rather than the deductive point of view. Cell permeability has been shown to depend on and vary with the mineral salt content of the cell; excess of calcium lessens the permeability, while too much sodium or potassium increases it, sometimes to the point of cell dissolution. Moreover, research has revealed the presence of a substance in the liver capable of producing a severe toxaemia. In dogs, where hepatic disease has been caused by ligature of the common bile duct or by other administration, a protein of hepatic origin has been demonstrated in the urine, and there is a decrease in calcium with an increase in the sodium content. Larsen believes that this alteration in mineral balance is responsible for an increase in cell permeability, with a resultant outpouring of the cellular contents, and finally of toxic bodies. He suggests that eclampsia and hyperemesis have the same etiological factors, and that eclampsia occurs in women who have survived hyperemesis in the first three months, but who have eventually been overcome by the cumulative effect of the same causes. Endocrine upset, especially of the parathyroid and thyroid glands, may cause a deficiency both in calcium metabolism and in neutralization of toxic wastes, while in normal pregnancy the maternal calcium may be used up to a great extent by the foetus. This may bring about increased cell permeability, with the discharge of glycogen, and later of toxic liver products into the system. In treating such cases, therefore, Larsen suggests that the administration of calcium lactate and parathormone and a parathyroid preparation should be combined with glucose and alkalis. The work of Mendel and Benedict shows that in human physiology calcium and magnesium are compensatory and complementary to one another. He suggests, therefore, that the success attending the treatment of eclampsia by magnesium sulphate depends largely on the resulting increase in cell calcium with decreased permeability. Ultra-violet rays, by promoting retention of the body calcium, have also a place in the treatment of the pregnancy toxaemias.

Pathology.

476. Avian Pollution of Drinking Water.

IN order to determine the part played by birds in the pollution of water supplies, I. E. MINKEWITSCH (*Zeit. f. Hyg. u. Infektionskh.*, October 12th, 1929, p. 506) has conducted a limited investigation on the bacterial flora of the intestine of different groups of birds, paying particular attention to the presence of *B. coli*. His first group, domesticated land birds, consisted of 10 fowls and 2 pigeons; *B. coli* was found in 9 of the fowls and in one pigeon. His second group, domesticated water birds, consisted of 17 ducks and 5 geese; *B. coli* was found in all the geese and in 15 of the ducks. His third group, wild forest birds, consisted of one raven, 4 wrens, 3 crossbills, 3 coletits, 2 woodpeckers, and one creeper (species not identified); *B. coli* was found in the raven—a carrion eater—but in none of the other birds, which feed on insects and plants. A most noticeable feature of this group was the paucity of bacteria in the intestinal canal; in 5 cases, in spite of generous inoculating, the cultures remained sterile so far as bacteria were concerned. His fourth group, wild water birds, consisted of 9 seagulls, 15 sea swallows, and two species of duck; *B. coli* was not found in any of the sea swallows, but was present abundantly in nearly all the other birds. The absence of *B. coli* from the intestine of sea swallows is probably due to their living solely on fish; seagulls, on the other hand, are not clean feeders. Analysis of the 46 strains of coliform bacteria recovered, giving acid and gas in lactose and a positive indol reaction, showed that 78 per cent. belonged to the species *B. coli*, 2 per cent. to the species *B. aerogenes*, while the remainder had properties intermediate between these two organisms. It would appear as if birds which do not come into contact with man and animals do not harbour *B. coli* in the intestine. The sanitary importance of birds in the pollution of drinking waters must therefore depend on the particular type of bird that is frequenting the water supply.

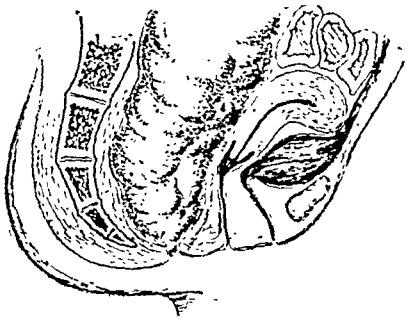
477. The Etiological Significance of Humoral Changes in Cancerous States.

R. REDING (*Bruxelles-Méd.*, October 20th, 1929, p. 1419) holds the view that the most important causal element in the pathogenesis of tumours is individual predisposition. He considers that local provocative causes, such as chronic irritation, only act by determining the localization of a neoplasm, the accelerated mitotic division being dependent on humoral alterations. These alterations are said to be of endocrine origin, the most evident being those which show a deficiency in the biological regulators of cellular division. The laws which govern ordinary cell division appear to hold good for malignant cells also. Other humoral changes consist of alterations in the sugar regulating mechanism, in the acid-base equilibrium, and in the ionic equilibrium. These alterations are independent of the presence of the tumour, and constitute a general predisposition on the part of the patient, as they precede the appearance of the cancer. This predisposition is considered by the author to be definitely inherited. The alkalosis found in cancerous patients is due to a breakdown of the original neutralizing mechanism. In support of this theory the author found that great differences are present in patients who have been operated upon and those who have been treated by gamma rays. In the first case the patient, even after removal of the actual tumour, remains cancerous from the humoral point of view. In the second case the patient treated by radiations becomes normal, not only in the sense of the disappearance of the tumour, but also from the humoral point of view. The gamma rays therefore appear to have a lasting influence on the regulators of cell division. A relapse, as evidenced by humoral alterations, coincides with, and even seems to precede, the recurrence of the tumour *in situ*, and therefore constitutes a useful method of early diagnosis.

478. Experimental Pulmonary Tuberculosis following Intestinal Infection.

LOPO DE CARVALHO, C. VIDAL, and NUNO DOS SANTOS (*C. R. Soc. de Biologie*, October 18th, 1929, p. 206) have repeated on the monkey some experiments on which Lopo de Carvalho and Ferreira de Mira performed two years ago on the dog. These workers found that if human tubercle bacilli were introduced into the duodenum of a dog which had been subjected to laparotomy they rapidly invaded the tracheo-bronchial glands, where they could be demonstrated by guinea-pig inoculation. When carmine or Indian ink was introduced into the duodenum, the colouring matter was later found in the lungs and in the tracheo-bronchial glands; it was [illegible] in the duodenal vein, but never in the [illegible] experiments suggested that the carriage of bacilli and inert particles from the intestine to the tracheo-bronchial glands occurred by the blood stream. This conclusion was supported by the demonstration of tubercle bacilli in the duodenal vein in animals that had been injected intraduodenally with these organisms. In an attempt to repeat these experiments on an animal more susceptible than the dog the present authors anaesthetized a monkey and made it swallow, by the help of a sound, a gelatin capsule containing 10 mg. of human tubercle bacilli from a culture. Some weeks later the animal showed symptoms of illness and was killed. The lungs were found to contain a multitude of semi-translucent miliary tubercles; the regional glands were also affected, but the other viscera were normal. A second monkey infected by the same method and killed at an earlier stage of illness showed similar lesions, but of less intensity. The authors considered that the pulmonary lesions resembled those produced by intravenous inoculation; they therefore conclude that the tubercle bacilli gained access to the lungs from the intestine by the blood stream.

The Menace of the Overloaded Bowel



always present, easily becomes serious in women. It causes interference with the pelvic circulation and tends to produce congestion of the uterus, not infrequently followed by functional disorders, producing dysmenorrhœa, menorrhagia, and even inflammatory conditions.

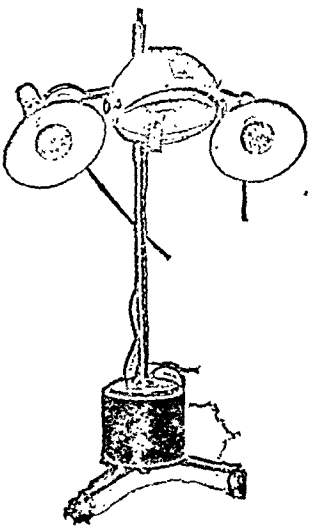
AGAROL Brand Compound gives relief and frequently permanently restores the functional activity of the colon. One tablespoonful before retiring, gradually decreased as improvement takes place, is especially well adapted for the treatment of constipation in women, because of the gentle action of Agarol Brand Compound and absence of irritation from its use.

A liberal trial quantity at the disposal of physicians.

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) [illegible] flavouring, free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea, not habit forming.



Two Sollux 500 Units fitted to Stand Model Hanovia Alpine Sun.

Sollux 500.

Per Unit - - £7

Complete for any supply.

COMPLETE YOUR LIGHT CLINIC

"I have always insisted on the importance of the complete solar spectrum as a therapeutic entity."
Dr. ROLLIER.

The great value of ultra-violet therapy is multiplied by the addition of luminous heat rays. The new Sollux 500 Units now enable this treatment with any quartz lamp. This combination ideally facilitates the administration of the complete spectrum therapy emphasized by Dr. Rollier and other specialists. You can now instal this indispensable supplement to your equipment at a minimum cost.

An ACHIEVEMENT IN SCIENTIFIC CONSTRUCTION

"EMESEY POPULAR" MODEL OPERATING TABLE
£45
100% BRITISH.

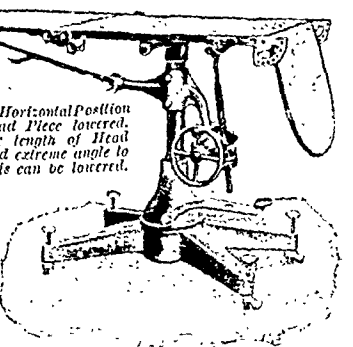

Table in Horizontal Position with Head Piece lowered. Note the length of Head Piece and extreme angle to which this can be lowered.

ESSENTIALLY similar in design to our well-known "Universal" Model. By the experience gained in its manufacture, and the use of modern methods of production, we are able to offer a first-class heavy and stable Table at a price within the reach of the smaller Hospitals and Nursing Homes.

Its range of movements makes it suitable for any operation required by Modern Surgery.

The perfection of its design has been proved by the unqualified commendation expressed by users of the original model of which the Popular Model is an offspring.

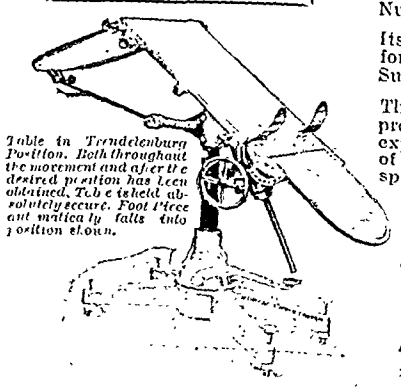

Table in Trendelenburg Position. Both throughout the movement and after the desired position has been obtained, Table is held absolutely secure. Foot Piece automatically falls into position shown.

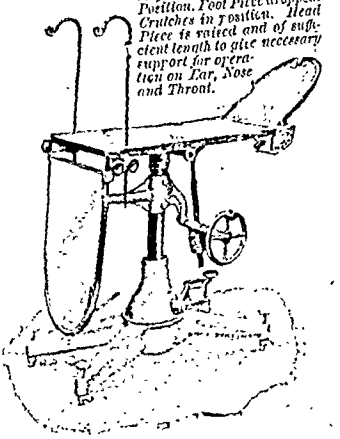

Adjustment for Lithotomy Position. Foot Piece dropped. Crutches in position. Head Piece is raised and of sufficient length to give necessary support for operation on Ear, Nose and Throat.

SEND FOR DESCRIPTIVE BOOKLET (B) or call at any of our Showrooms for demonstration.

Salt and Son Ltd.

Five Essentials of an Artificial Leg

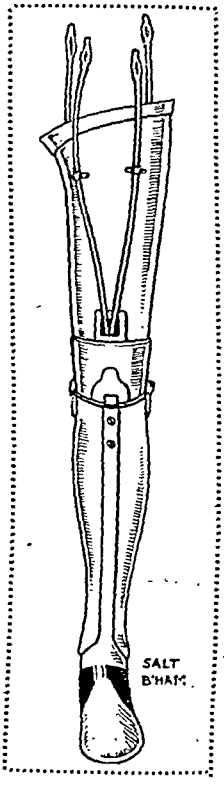
SALT'S LIGHT METAL LIMB FOR ABOVE KNEE AMPUTATION.

This illustrates one of our many artificial legs. When fitted by us it possesses the FIVE essentials mentioned.

Made of duralumin with wooden foot, it weighs only 3¼ lb. for an adult male patient.

We manufacture wooden, leather, and metal limbs for all types of amputation, and can send expert fitters to any part of the country.

Illustrated lists sent on request.



Comfort is naturally the first consideration.

Lightness reduces the physical strain to a minimum.

Action governs rapidity of movement and natural gait.

Appearance is maintained when made to match the fellow limb.

Simplicity in construction lessens cost and maintenance.

SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

300, HIGH HOLBORN, LONDON, W.C.1.

This preparation is now obtainable in 5-oz. bottles.

MIST. HEPATICA CONC. (Hewlett's).

Composition.—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.
This preparation does NOT come under the Dangerous Drugs Act.

THIS excellent compound has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease, and in pregnancy or in the constipation due to sedentary habits, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient, and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz.; 10-oz.; 22-oz.; 40-oz; and 90-oz. Bottles. Price in England, 12/6 per pound.
This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

Vapo-Cresolene Est. 1879
Sold by all Chemists
Write for descriptive Booklet No. 39D.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.
This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

EATAN

Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non Irritant. Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 10/8 bottles.

Special Terms to Hospitals.

THE TREATMENT OF RHEUMATOID ARTHRITIS

THIS disease, which the medical man is increasingly called upon to combat, may be successfully treated by the correct application of Pistany radio-active Mud Packs.
The packs can be applied in the patient's own home if necessary, and the treatment may be successfully combined with other physiotherapeutic methods.
Pistany (Czecho-Slovakia) offers the most effective treatment for the cure of rheumatoid arthritis. The properties of Pistany's hot volcanic soft mud are quite peculiar. During the season over 26,000 visitors go to this picturesque Spa, and statistics show that of 100% of patients, only less than 5% do not respond to the treatment—30% are completely relieved and 65% are considerably improved.
Home treatment can never supersede the cure at the Spa.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

BELVOIR NURSING HOME,

ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

COLONIAL MEDICAL SERVICES.

Vacancies exist at present for Medical Officers in:—

(*a*) The East African Medical Service.

(*b*) The Malayan Medical Service.

QUALIFICATIONS.

Applicants must be British subjects of European parentage, and between 22 and 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held hospital or public health appointments, or who have special knowledge of anæsthetics, radiology, surgery, medicine, ophthalmology, gynæcology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

SALARIES.

East Africa. £600 per annum, rising by annual increments of £30 to £840 per annum, and thence, subject to an efficiency bar, by increments of £40 to £920 per annum.

Malaya. $500 a month (£700 per annum, at exchange Straits $1=2s. 4d.), rising by annual increments of $25 a month (£35 per annum) to $800 a month (£1,120 per annum).

In addition to salary, there is at present a non-pensionable temporary allowance of 10 per cent. of salary to unmarried officers and 20 per cent. to married officers.

CONDITIONS OF SERVICE.

Appointments are made on probation (two years in the case of East Africa and three years in Malaya) in the first instance. At the end of the probationary period the officer may, if his services have been satisfactory, be confirmed in his appointment and placed on the permanent establishment.

QUARTERS.

East Africa. Free quarters are provided or an allowance is given in lieu.

Malaya. Quarters are usually available and are provided at a rental which in no case exceeds 6 per cent. of the officer's salary.

PASSAGES.

(Applicable to both East Africa and Malaya.)

Free first-class passages are provided both on first appointment and when proceeding on leave.

Further particulars and forms of application may be obtained on application in writing to the PRIVATE SECRETARY (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

Corporation of Durban, SOUTH AFRICA.

APPOINTMENT OF MATRON, DURBAN INFECTIOUS DISEASES HOSPITAL.

The undersigned are authorised to receive applications for the above post.

The salary will be at the rate of £254, rising by annual increments of £15 to a maximum of £294 per annum, plus free quarters, boarding, laundry, and uniform.

Candidates to be general and fever certificated nurses between the ages of 30 and 35 years, and must have had experience in the "cubicle" system of nursing infectious diseases.

Preference will be given to a candidate now holding, or who has recently held, a post as Sister in a fever hospital which is a recognized training school for fever nurses.

The successful candidate will be required to sign a contract for a period of three years, subject to renewal.

Medical certificate of fitness will be required.

First-class passage will be paid by the Town Council, and salary will commence on the date of assumption of duties at the Hospital.

The appointment will be subject to the Durban Town Council's Regulations re leave and conditions of service from time to time in force.

Applications, accompanied by copies of testimonials of recent date, must be forwarded to the offices of the undersigned not later than Saturday, December 7th.

By Order,
WEBSTER, STEEL & CO.,
9, St. Helen's Place, Bishopsgate, London, E.C.3. Agents to the Durban Corporation.

The Radium Institute.

Riding House Street, London, W.1.

Applications are invited for the post of HOUSE SURGEON. Candidates must be fully qualified and unmarried, and the appointment is for a term of twelve months as from January 1st, 1930.

The salary will be at the rate of £150 per annum, with board, lodging, and laundry.

Applications, stating age, qualifications, and experience, with copies of three recent testimonials, must be received at the Institute not later than December 7th.

Canvassing, either directly or indirectly, is not permitted.

THOS. A. GARNER, Secretary.

The King Edward VII Welsh NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered Medical Practitioners for the post of AREA ASSISTANT TUBERCULOSIS PHYSICIAN. Salary £600 per annum, together with travelling and subsistence allowances when absent from base. Preferably candidates should have *had at least six months' special training in* Tuberculosis, with eighteen months' experience in general clinical work, of which six months should have been spent in a Hospital not confined to the treatment of Tuberculosis.

Applications, stating full qualifications and previous experience, together with copies of three recent testimonials, should reach the undersigned not later than November 30th.

Memorial Offices, Westgate St., Cardiff. D. A. POWELL, Principal Medical Officer.

Perthshire Joint Medical Service SCHEME.

A FIRST ASSISTANT MEDICAL OFFICER (male) is required under the above Scheme in the County of Perth.

The possession of a D.P.H. and Hospital experience are essential. Experience in any branch of Public Health, including Tuberculosis and School Medical work, will be added recommendations. Salary £600 per annum, rising by annual increments of £25 to £750, subject to satisfactory service.

Forms of application may be obtained from the undersigned, with whom completed applications, accompanied by copies of three recent testimonials, should be lodged not later than December 6th.

County Buildings, Perth. Dr. D. J. McLEISH, Medical Officer of Health.

City of Birmingham.

MATERNITY AND CHILD WELFARE DEPT.

RESIDENT MEDICAL OFFICER.

A Resident Medical Officer is required on January 1st next, for a period of six months, for the CITY BABIES' HOSPITAL (50 beds). Salary at the rate of £150 per annum, with board and laundry. Previous experience in a Children's Hospital desirable. Apply, giving all particulars of qualifications, age, and experience, to the Medical Officer of Health, the Council House, Birmingham; on or before Thursday, November 28th.

Board of Education.

APPOINTMENT OF MEDICAL OFFICER.

The Board of Education invite applications from registered Medical Practitioners (men) for one vacant appointment as Medical Officer on the staff of the Board.

Applicants must be Medical Men, preferably between 30 and 40 years of age, with a University Medical degree, a Diploma in Public Health, and experience of the School Medical Service.

The officer will be required to reside in London or such other area as may be assigned to him by the Board. The appointment will carry the normal Civil Service conditions as to pension, holidays, etc.

The salary will be £600 per annum, rising by annual increments of £25 to a maximum of £900, together with the usual Civil Service bonus. The bonus on the minimum salary is at present £176 7s. In special circumstances the *minimum* salary may be advanced where a candidate has special knowledge and experience.

Applications should be submitted on the prescribed form, copies of which may be obtained from the Director of Establishments, Board of Education, Whitehall, S.W.1.

Applications must reach the Board not later than Saturday, *December 14th.*

Greenwich Union.

GREENWICH & DEPTFORD CHILDREN'S HOMES; SIDCUP.

DENTIST.

The Guardians invite application for the appointment of DENTIST at the above *Homes* from duly qualified Dental Surgeons.

The candidate appointed will be required to carry out *Dental* treatment when necessary for any particular child and to *examine* every child in the Homes at least one in three months and afford treatment where needed. Remuneration £74 per annum, subject to deduction under the Poor Law Officers' Superannuation Act, 1896.

Applications to be made on forms to be obtained at the Guardians' Offices, Board Room, Woolwich Road, E. Greenwich, and they should be returned to the same address not later than December 10th.

Canvassing the Guardians, either directly or indirectly, is prohibited and will disqualify.

By Order,
W. C. CORNISH,
Clerk to the Guardians.

November, 1929.

ROYAL NAVAL MEDICAL SERVICE.

,, 18 ,, ,, ...	£2,250

Rates of Pension range from £423 a year, normally earned after 20 years' service, to £1,123 a year, the maximum earned by a Surgeon Vice-Admiral.

Copies of the Regulations and Particulars as to Conditions of Service and Emoluments may be obtained on written or personal application to the Medical Director General of the Navy, Queen Anne's Chambers, Tothill Street, London, S.W.1.

Egyptian Government.

EGYPTIAN UNIVERSITY.

FACULTY OF MEDICINE.

Applications are invited for two posts as SURGICAL TUTORS.

The salary offered is £E.35 a month in Grade V, and the appointment will be on contract for one year, renewable at the end of that time. The appointment is to be a full-time post.

The candidates must be Egyptians, and preference will be given to those possessing the F.R.C.S. England.

Applications, accompanied by testimonials and references, should be addressed to the DEAN, Egyptian University, Faculty of Medicine, Cairo, so as to be received not later than December 15th, 1929.

Ministry of Health.

The Minister of Health invites applications from registered *Medical Practitioners (men)* for five vacant appointments as MEDICAL OFFICERS on the staff of the Ministry.

The salary commences at £700 per annum and rises by annual increments of £25 to £1,000 per annum. In addition to the salary a bonus, which varies with the cost of living, is payable; the bonus on the minimum salary is at present £187 3s. and is next subject to revision on March 1st, 1930.

The appointment will carry the usual Civil Service conditions as to pension, holidays, etc.

Candidates must be Medical Men of not less than seven years' standing, and be experienced in Public Health, Poor Law, or Preventive Medicine work.

A Medical Officer is required to devote his whole time to the Public Service, and must be prepared to work in any part of England or Wales if required to do so.

Canvassing Members of Parliament or Officers of the Ministry will render a candidate liable to disqualification.

Forms of application, with further particulars [illegible]e obtained from the Ministry of Health,

[illegible]onsidered unless received on the prescribed form not later than *December 7th*, 1929.

Essex County Council.

APPOINTMENT OF MEDICAL OFFICER AT COUNTY SANATORIUM.

The County Council of the Administrative County of Essex invite applications for the appointment of Resident Medical Officer at their Sanatorium for the treatment of Tuberculosis, now in course of erection at Black Notley, near Braintree, from registered Medical Practitioners, not more than 45 years of age, who are experienced in the treatment of pulmonary and non-pulmonary Tuberculosis, particularly in the latter, and who have had experience in the treatment of Orthopædic cases.

The institution, when completed, will provide accommodation for the treatment of approximately 174 cases of pulmonary and non-pulmonary tuberculosis, and for 10 orthopædic cases.

The salary attached to the appointment will be *at the rate of £650 per annum, together with* the use of an unfurnished house, rates, and Schedule A tax free, water, light, laundry, coal, and such garden produce for the needs of the household as may be available from the grounds of the Sanatorium after the requirements of the institution have been met, and will rise, subject to satisfactory service, by annual increments of £25 to £850 per annum. The foregoing emoluments are valued at £150 per annum.

The person appointed will be required to devote his whole time to the service of the Council, and under the control and supervision of the County Medical Officer of Health, to perform such duties and to furnish such advice and assistance appertaining to his office as may be required, and to assist in such other of the *County medical work as he shall have time and* opportunity for performing. The appointment will be subject to three months' notice on either side.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, *which will not be returned, should be addressed* to me and delivered at the Shire Hall, Chelmsford, not later than 10 a.m. on Saturday, November 30th.

JOHN H. GOOLD,
Clerk of the County Council.

Shire Hall, Chelmsford.
November 8th.

City of Leeds.

CHIEF ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from qualified and registered Medical Practitioners for the post of Chief Assistant Medical Officer of Health for the City of Leeds. Candidates must not be more than 40 years of age and, in addition to previous experience in Public Health administra*tion, should also have had experience in one or more of the special branches of Preventive* Medicine, e.g., School Medical work, Tuberculosis, Maternity and Child Welfare, etc.

The person selected will be required to devote his whole time to the office, and to perform such duties as are allotted to him by the Medical Officer of Health. It will be necessary for him *to enter into an agreement of service with the* Corporation, terminable by three months' notice on either side, and to pass a medical examination and contribute to the Superannuation Fund established under the Local Government and Other Officers Superannuation Act, 1922.

The salary will be £900 per annum. Applications, stating age, qualifications, and experience, together with copies of three testimonials, endorsed "Chief Assistant Medical Officer," must be delivered at my office, 26, Great George Street, Leeds, *not later than December 6th.*

THOS. THORNTON,
Town Clerk.

Town Hall, J. HENRY FIELD,
Huddersfield, Town Clerk.
November 18th, 1929.

County of the Isle of Ely.

APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The County Council invite applications for the post of Assistant County Medical Officer of Health and Assistant School Medical Officer.

The salary will be £600 per annum, together with the repayment of travelling expenses according to the County Council's scale, and the appointment will be terminable by three months' notice, in writing, on either side.

Experience in eye work and the conduct of refractions is desirable and will be deemed an additional qualification for the post.

The present officer also holds the appointment of Medical Officer of Health under the Whittlesey Urban District Council, at a salary of £100 per annum.

Applications, with copies of not more than three recent testimonials, must be forwarded to the undersigned, before December 7th, on a form which may be obtained from the undersigned.

County Hall, C. E. F. COPEMAN,
March. Clerk of the County Council.
November 15th, 1929.

County Borough of Blackburn.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners for the post of Assistant Medical Officer (male), who will act under the supervision of the Medical Officer of Health and the School Medical Officer.

The person appointed must devote the whole of his time to the service of the Corporation.

The duties of the office will consist largely, but not exclusively, of work in the School Medical Department.

The salary will be £600 per annum, to be increased by annual increments of £25 to a maximum of £700 per annum, no bonus will be payable.

Forms of application and further particulars of the duties and conditions of the appointment may be obtained from the Medical Officer of Health, Victoria Street, Blackburn.

Completed forms, accompanied by copies of three recent testimonials, must reach me by Saturday, December 14th, and should be endorsed on the envelope "Assistant Medical Officer."

Canvassing will disqualify.

Town Hall, LEWIS BEARD,
Blackburn. Town Clerk.
November 18th, 1929.

Obesity and its Treatment

"INKRETAN"

A brominated preparation of Thyroid and Pituitary Glands of standardised potency. Each "Inkretan" tablet contains 0.2 mgm. of Iodine in specific combination as Thyroglobulin.

"Inkretan" tablets are standardised by the gaseous metabolism method—therefore constant in action.

Prof. Carl von Noorden reports:—

> "For specific reasons preference is given to 'Inkretan' tablets, which are standardised by the Iodine content. They permit of easy graduation of the effective dose, and in suitable cases show good powers of activity."

Special Literature supplied on request, with summary of treatment and suggestions as to diet.

"Inkretan" tablets supplied in bottles, each 25 or 50.
A bottle will be sent free on request.

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received recently.

Messrs. KAYLENE, LTD. April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

Literature and supply for clinical trial obtainable from the manufacturers.

Diphtheria Antitoxin

(Parke, Davis & Co.)

¶ Parke Davis & Company have been engaged in the preparation of serums and antitoxins since 1894. Many years' experience, coupled with the possession of ample facilities and the collaboration of specially trained scientific workers, place the firm in a particularly favourable position for the supply of thoroughly trustworthy preparations of this class.

A constant effort has been made to improve upon past achievements. Special study has been directed towards the elucidation of many problems affecting the quality of an antitoxin—the most suitable culture media, methods of producing toxin of highest virulence, immunising procedures, reduction in volume of the dose and also the elimination of undesirable proteins—in all these matters great improvement has been effected.

¶ Diphtheria Antitoxin (P., D. & Co.) is unsurpassed as regards water-whiteness, sparkling transparency and low content of solids. Of even greater moment is the reduction to a remarkably small percentage of those protein elements of the serum which are held to be responsible for serum sickness and kindred protein disturbances.

¶ Two grades of Diphtheria Antitoxin (P., D. & Co.) are offered, viz., Standard and Special. These differ only in the volume in which the same number of antitoxin units is presented. The "X" or "Standard" serum contains approximately 1,500 antitoxin units per c.c.; "XX" or "Special" serum 2,250 to 2,750 antitoxin units per c.c.

Further particulars of this serum and of biological products for the Schick Test and for diphtheria prophylaxis will be sent on request.

D PARKE, DAVIS & COMPANY 50 BEAK ST., LONDON, W.1.

The Therapeutic value of BRANDY–

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.

Take no risks; ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe MARTELL'S BRANDY

and know that you are doing the best possible for your patients.

THE GREATER STRENGTH

J. & A. CHURCHILL

NEW (SECOND) EDITION. 115 Illustrations. 15s. Postage 9d.

OGILVIE'S RECENT ADVANCES IN SURGERY

"We confidently expect further editions of this admirable book."—BRITISH MEDICAL JOURNAL.

"The revision of this useful book has been well done, and the reader who depends upon one manual to keep him abreast of surgical thought will find that the author has not failed to record any of the important advances in surgical science since the first edition was published. Even more assiduous readers of surgical literature will be grateful for the admirable summaries of various topics of interest here set out. The book is a discriminating account of what has happened in recent years and well deserves its title. . . . The author has shown wise judgment both in his selection of material and in the manner of its presentation."—THE LANCET.

FIFTH EDITION. 1,051 pages. ONE GUINEA. Postage 1s.

STARLING'S PHYSIOLOGY

Edited and Revised by C. LOVATT EVANS, D.Sc., F.R.C.P., F.R.S., Jodrell Professor of Physiology in University College, London. With chapters on the Central Nervous System and Sense Organs revised by H. HARTRIDGE, M.A., M.D., Sc.D., F.R.S., Professor of Physiology, St. Bartholomew's Medical College.

NEW SECOND EDITION. 2 Plates and 12 Illus. 15s. Post. 6d.

CAMERON'S TEXTBOOK OF BIOCHEMISTRY

For Students of Medicine and Science.

By A. T. CAMERON, D.Sc., F.I.C., F.R.C.S., Professor of Biochemistry, University of Manitoba.

4 Plates. 23 Text-figures. 8s. 6d. Postage 6d.

A COURSE IN PRACTICAL BIOCHEMISTRY

By A. T. CAMERON, D.Sc., and FRANK D. WHITE, A.R.T.C., Ph.D.Edin. F.I.C., Asst. Professor of Biochemistry, Faculty of Medicine, University of Manitoba.

NEW FIFTH EDITION. 14 Illustrations. 8s. 6d. Postage 4d.

LAWRENCE'S THE DIABETIC LIFE:

Its Control by Diet and Insulin.

SECOND EDITION. 674 Illustrations. Two Volumes. 28s. Postage 1s. 3d.

ROMANIS & MITCHINER'S

SCIENCE AND PRACTICE OF SURGERY.

"A well-balanced account of the Science and Art of Surgery as practised at the present day. There was room for this textbook, and the authors are to be congratulated upon the production of a very useful and practical manual for the undergraduate student. The price is very moderate."—THE LANCET.

THIRD EDITION. 65 Illustrations. 15s. Postage 9d.

CLARK'S APPLIED PHARMACOLOGY

By A. J. CLARK, M.C., M.D., F.R.C.P., Professor of Materia Medica and Pharmacology, University of Edinburgh.

SEVENTH EDITION. 2 Vols. 900 Illustrations (43 in Colour). 70s. Postage 1s. 3d.

ROWLANDS & TURNER'S OPERATIONS OF SURGERY

"This is probably the most important modern textbook on Operative Surgery published by British Surgeons. "The volumes are not only safe as a book of reference, but of the greatest value to the general surgeon. The searching and detailed revision which has been carried out in the last edition does great credit to the ability and industry of the authors."—PRACTITIONER.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1

THE EXTRA PHARMACOPŒIA

By W. HARRISON MARTINDALE, Ph.D.

Nineteenth Edition. *In Two Volumes.*

Vol. I (1928) deals chiefly with Treatment, giving the important issues as to CLINICAL USE of all modern CHEMICALS and DRUGS, characters, dosage, methods of prescribing, etc.

Vol. II (1929) COMPLETES THE SET. It is concerned with INVESTIGATIONS, EXPERIMENTAL RESEARCH, DIAGNOSIS, and a large amount of new matter in medicine and allied sciences.

BRIT. MED. JOURN., Nov. 2nd, 1929, says: *"Has a well-established reputation as a most useful and convenient work of reference."* LANCET, Nov. 2nd, 1929, says: *"A clear and authoritative publication of the highest value."*

An up-to-date Book for everything on the Therapeutic Use of Drugs. It embodies the Latest and Most Varied Information on Chemistry, Pharmacy, Therapy, and numerous other subjects.

Both Vols. together to any part of the world, 50/- net, post free. **Vol. I,** 27/6 net; postage 6d. **Vol. II,** 22/6 net; postage 1d.

LONDON: H. K. LEWIS & CO., LTD., 136, Gower Street, W.C.1

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in associ[illegible] bequeathed to us by the older master[illegible]

"The most valuable and comp[illegible] Cardiology with which we are[illegible] JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology, for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, [illegible] wealth of practical information. Obviously based [illegible] experience and investigative work."—SU[illegible] OBSTETRICS (Official Journal of the Americ[illegible]

"Dr. Price is to be congratulated again on the reappearan[illegible] second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

Wear Socks of handsome ingrain shades

The Two Steeples No. 83 Socks are made from ingrain yarns full of character. Only St. Wolstan Wool is used, the highest grade pure botany. It is dyed in the wool before spinning, in various separate but harmonious colours in the necessary proportions for each shade, then drawn together and spun into yarn.

The colours blend in the drawing and spinning, resulting in heathers, browns, greys, lovats, etc., of handsome appearance, which are an outstanding feature of the '83' range.

Ask your hosier for these socks—there's a shade for every suit.

SALTAIR SURGICAL SERVICE

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

The Medical Profession with the aid of Salt's Surgical Service CAN

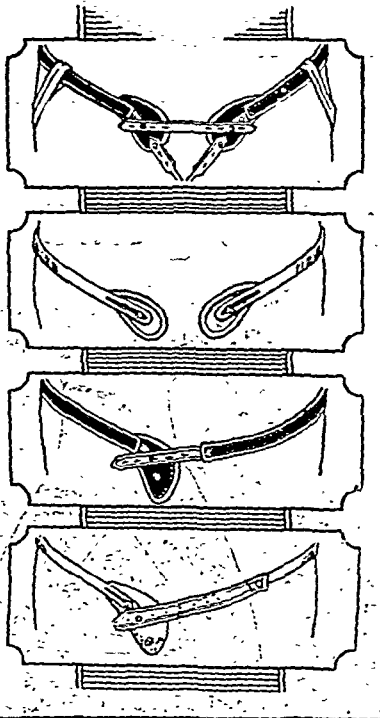
(except in cases of gross carelessness on the Patient's part)

PREVENT

future cases of

SEVERE HERNIA

and greatly alleviate [illegible] existing.



HIGH PRICES NOT ESSENTIAL FOR EFFICIENCY.

An outstanding feature of our Surgical Service is that, taking into consideration price, occupation, and the characteristics of each individual case, we can supply every class of patient with an *Efficient Truss.*

Our Hospital quality truss has the fundamental merits of the more expensive trusses, but is finished with a cheaper covering, etc., which enables us to supply this at a price which is suitable to the poorer class of patients.

Our Ordinary quality truss has a leather lining and covering which proves most durable in cases subjected to hard usage, and has the added advantage of being low in price.

For the patient who is thin, or who requires strong pressure, we supply different types of soft indiarubber pads while for the man who suffers from excessive perspiration our celluloid truss is especially suitable.

We invite the Medical Profession to compare our prices for special trusses with the high prices charged for so-called "rupture-cure" appliances so extensively advertised to the general public.

A special food for changing the intestinal flora

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of h s slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs.

Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State, COATES & COOPER, 41, Great Tower Street, London, E.C.3.

THERE is one care: one protection against infection and disease that every mother and child should have. That is the protection of Marshall's Lysol—the antiseptic that is safe and sure for every case.

Marshall's Lysol is the only Lysol made from the original formula. A doctor who recommends Marshall's Lysol KNOWS that his patients will obtain a Lysol of unvarying strength and quality. That this is vitally important we need not stress. Every doctor and nurse knows that in midwifery, surgery, or cases of infectious disease, the highest grade antiseptic is absolutely essential.

VITAD PALATINOIDS

¶ VITAD is the unsaponifiable fraction of Cod-Liver Oil containing in a high concentration Vitamins A and D.

¶ While presenting practically the full medicinal properties of Cod-Liver Oil, it is free from the nauseating oily fraction. Being exhibited as a Palatinoid, it is protected by the hermetically sealed non-actinic covering from all chance of oxidation and light action, thus ensuring a standard dose at all times.

¶ Palatinoid Vitad is put up in bottles of 25 and 100, and in two strengths:

m. 1½ for Children
m. 3 for Adults.

Two palatinoids respectively represent the full daily dose of Vitamins A and D.

Manufacturers of Roboleine.

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

BY APPOINTMENT

NEARLY A CENTURY AGO THEY WON FAME . . . TODAY THEY ARE MADE WITH THE SAME EXCLUSIVE CARE

THE exceptional care and exclusive conditions under which Brand's Essences are made, first brought them fame nearly a century ago. Mr. Brand himself, in collaboration with a famous doctor, evolved the process by which the juices of meats are extracted and made available to the public in a convenient and hygienic form.

Brand's Essences are the pure juices of the finest chickens, beef and mutton. No preservatives are added—the pure amber jelly containing the stimulating properties of the meat—goes straight to the consumer.

Brand's Essences are invaluable for all states of convalescence. They can be taken in small quantities, are easily swallowed and excite the appetite. The digestive organs absorb them rapidly without strain.

Brand's Essences (Beef, Chicken and Mutton) are obtainable at chemists and stores throughout the world in small and large-sized tins and jars. Brand & Company Limited, Mayfair Works, South Lambeth Road, London, S.W.8.

BRAND'S ESSENCES

BOOTS PRODUCTS

Acriflavine (BOOTS)

One of the most potent of modern antiseptics, physiologically pure and extremely soluble in water. ACRIFLAVINE (BOOTS) kills organisms in a concentration of 1 in 100,000. Its potency is actually increased when brought into contact with serum. Now recognised as the routine preparation for irrigations in the treatment of gonorrhœa. Ideal for suppurating wounds and septic conditions of all kinds.

ACRIFLAVINE (BOOTS) is supplied in 5 gm. and 20 gm. bottles, and in tablets (1.75 gr. and 2.187 gr.).

NEUTRAL-ACRIFLAVINE (BOOTS) is specially prepared for internal use in the form of enteric-coated tablets, and also for hypodermic or intravenous injections.

NEUTRAL-ACRIFLAVINE (BOOTS) is supplied in 5 gm. and 20 gm. bottles; in tablets (1.75 gr.) and in enteric-coated tablets (½ gr.).

PRACTICAL PROPHYLAXIS AGAINST

Common Colds and Catarrh

Save valuable time in prevention and treatment by using

MULFORD-SEROBACTERINS

(Antigen and Antibody Combinations)

Some immediate protection afforded.
Highest Antigenic Value.
Cause less local and systemic reaction because method of preparation reduces toxicity. Larger doses may be given and at shorter intervals.

CATARRH "COLDS" SEROBACTERIN, MIXED

(Sensitized Bacterial Vaccine)

This product differs from ordinary vaccines because it is "sensitized"—that is, the bacteria have previously been treated with homologous immune serum, from which have been absorbed quantities of their respective antibodies. No serum is present in the preparation, however, the bacteria having been washed completely free of it. A degree of immediate passive resistance is conferred by injection of the serobacterin, by reason of the setting free of some of the antibodies. This degree of resistance persists until active immunity has been established. The formula includes: Staphylococcus (aureus and albus), Streptococcus, B. Friedlander, Pneumococcus (Types I, II, and III), M. Catarrhalis.

Bowel Inertia

THE Physician is familiar with the patient who complains of headache, loss of appetite, depression, who is not suffering pain but is nevertheless conscious that his or her general health is far below the standard it should be.

Diagnosis often reveals auto-intoxication—the result of habitual constipation. The use of a suitable eliminant is indicated.

"Cristolax" proves exceptionally successful in such cases. It is composed of 50% of the purest [illegible] extract. The high diastasic quality of the pure malt extract gives material assistance to the digestive process which is often impaired in this condition, whilst the oil content lubricates the intestinal tract, keeps the fæces soft, and ensures their complete expulsion.

A delicious preparation in a clean, convenient dry form for infants, children, and adults.

A New Quinoline Derivative

for use in the

Treatment of Infection

A recent article (*The Lancet*, November 9th, 1929, p. 968) reported the discovery at Leeds University of an important new antiseptic

QUINANIL

or Anil-quinoline 48 S

Quinanil has been submitted to very thorough clinical trials at the General Infirmary, Leeds, and has been found to have qualities

"superior to those of any other similar substance. . . ."

It has high bactericidal value and low toxicity, and its solutions do not cause a permanent stain. Quinanil is manufactured in the laboratories of The British Drug Houses Ltd., and every batch is submitted to Leeds University for approval before issue.

Supplies are now available to members of the medical profession as follows:—

In boxes of 6 tubes, each tube containing 0.5 gram.

In bottles, each containing 2.5 gram.

Full particulars and prices are available on request

THE BRITISH DRUG HOUSES LIMITED. LONDON N-1 Quin 7

'PANOPEPTON'

WHAT IT CONTAINS.

Contains in solution, in an agreeable form, the entire nutritive constituents of beef and wheat.

Contains all that is digestible in beef—in its juice and in its muscle tissues.

Contains all that is digestible in wheat—its gluten, its carbohydrates.

Contains all the savory and stimulating elements, the extractives, the mineral constituents of beef and wheat.

Contains these constituents in the soluble, perfectly diffusible form into which they are converted in the process of normal digestion.

USES OF 'PANOPEPTON.'

Can be relied upon in cases where the nutrition of the patient is of prime importance.

Has saved the patient in desperate straits due to intolerance of food.

Has nourished and restored in many cases where the patient has steadily lost strength on other foods.

Possesses remarkably restorative and stimulating properties.

Is the most nutritious, the most agreeable and reliable—the BEST of all foods for the sick.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

SUPPLIED IN 12-oz. BOTTLES.

Local Anæsthesia in Surgical Practice

UNUNITED FRACTURE.

TYPICAL CASE.

H. C. A., aged 27 years.

Diagnosis: Ununited fracture of the right radius and ulna at the mid-point.

Operation: Intramedullary auto-transplant.

Anæsthesia: Brachial block, 10 c.c. of 2 per cent. Novocain-Adrenaline solution; local infiltration for removal of graft.

Operation: The patient was given ¼ grain morphine and 1/100 scopolamine at 9 a.m. At 10 a.m. the operation was performed. Brachial anæsthesia was established with the patient sitting in a chair, 10 c.c. of 2 per cent. Novocain-Adrenaline being used. A large rhomboid infiltration was then made on the anterior surface of the leg. The site of the fractures was then reached by two incisions and the ends of the bones freshened. With a large drill the narrow cavity was reamed out and dowels were prepared from bone removed from the tibia. These dowels were fitted into place, the wound sutured, and the patient made an uneventful recovery. The anæsthesia for the removal of the transplant was obtained by a subdermal infiltration of the leg and, in addition, the needle was carried down to the periosteum, making an infiltration along the line of the transplant to be removed.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

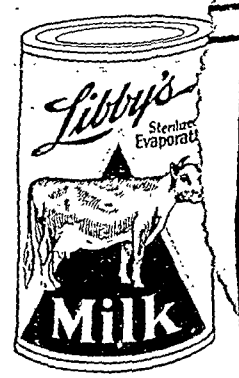
Healthy-happy and contented --

because rightly fed

Libby's Milk is a really safe food. Its quality never varies. When fed according to Libby's Feeding Table day by day it is building and firmly establishing the good health that always indicates the happy and contented Baby.

Libby's Evaporated Milk can be readily assimilated by the most delicate of Babies because it is sterilized, evaporated, "homogenized," and emulsified. This scientific process of milk production enables Babies immediately to obtain the full nourishment of milk, and makes Libby's as easily digested as Mother's milk.



Libby's

Evaporated
Milk

☆ **£1,000** *will be paid to any Hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.*

PLASMONA
THE BLOOD & NERVE FOOD

in Tablet Form

for the Dispensing Physician

is now supplied in Bottles of 1,000 Tablets

at a most favourable price.

Full particulars and Clinical Sample on request.

Standard Packings:

Bottles of 50 or 100 tabs.

Plasmona tablets may be given with full confidence as an alternative to Plasmona in powder form—i.e., in all cases where a highly active and reliable supplementary food and general tonic is indicated. Plasmona tablets are readily disintegrated and may safely be given to patients with the most sensitive digestions. The tablets may either be chewed or swallowed whole.

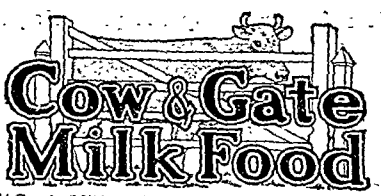
HUMAN TUBERCULOSIS OF BOVINE ORIGIN

At the recent B.M.A. Conference held in Manchester reference was made to this important subject, of which the following abstracts (Lancet, Oct. 19, 1929, p 824) are typical:—

"Dr. ———, M.O.H., in opening the discussion, estimated the human deaths caused annually by the bovine tubercle bacillus at 2,000 to 2,300. Most of them were the deaths of children, and we had no knowledge as to how many non-fatal infections occurred. As to the extent of bovine tuberculosis among cattle in this country, he thought that about 40 per cent. of the cows were infected; that about 1 per cent. of the cows were 'open' cases; and that about 0·3 per cent. had tuberculosis of the udder."

"Dr. ———, M.O.H., thought that 5 per cent. of the cows had diagnosable tuberculosis. He had found certified milk highly infected with tubercle bacilli. The graded milks were a failure, and pasteurisation was only doubtfully safe. He believed that milk dried by the roller process was the best solution, and he looked forward to the establishment of milk-drying factories throughout the country."



"Cow's Milk made safe and suitable for Baby."

This annual toll of human life, which is mostly confined to young babies, can be eliminated by a suitable heat treatment of the milk Processes such as pasteurisation have their limitations so far as the feeding of infants is concerned, particularly in view of their disturbing influence on the mineral and vitamin content of milk.

The bacteriological sterilisation of milk is assured by the COW & GATE Improved Roller Process, which also effects maximum preservation of the vitamin content with minimum disturbance of the mineral salts.

The makers will gladly supply samples for Clinical-test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time

OLDEST FRAGMENTS OF PAPER IN THE WORLD.—The art of paper-making was practised in China for centuries before it became known to the rest of the world. According to tradition, paper was made and used there in the second century B.C., but while there is no actual evidence of this, the fragments recently found and here reproduced provide proof that paper did exist in the first century A.D. Ts'ai Lun, a chamberlain of the emperor Ho Ti, is its reputed inventor, and the period to which the fragments are dated agrees very well with this supposition. Ts'ai Lun is said first to have substituted silk for the bamboo strips upon which the earliest Chinese documents were written, and then to have discovered a way of making paper of bark, tow, old linen, fish-nets, hemp, etc., by pounding these materials in a stone mortar and then compressing the pulp into sheets. The fragments here illustrated were found near a frontier station in the Great Wall. The portion of a letter, on the left, reads ....." prostrating himself, says ....wishes Mr. Hsieh Yung-ssû good health in all circumstances." In the fragment on the right may be read the words ....."as soon as the foot-soldiers arrived he sent ....." The art of paper-making seems to have reached the world outside China through certain Chinese prisoners who imparted it to their Arab captors in the eighth century A.D.

ANCIENT CHINESE BAS-RELIEF, ON WHICH IS DEPICTED THE CROW WITH THREE FEET FLYING DOWN TO EARTH TO FEED UPON THE DRUG OF IMMORTALITY—ONE OF THE MYTHS CONNECTED WITH THE IDEA OF THE PHILOSOPHER'S STONE AND LONGEVITY.—*If, as seems probable, the Chinese were* the first to practise the pseudo-science of alchemy, they were indeed important pioneers, for they gave to the world, through the Greeks and Arabs, the clues to chemistry, pharmacy and medicine. It is not easy to estimate the benefits conferred upon humanity by the early Chinese physicians, for definite dates are often lacking, and extravagant claims are made. Hua T'o (died A.D. 220), "the Asklepios of China," is said to have performed operations, using an anæsthetic composed probably of aconite and datura, and to have been the first to remove cataract. He seems also to have advised trepanning, under an anæsthetic, for a patient suffering from violent headaches. The Chinese claim to have practised inoculation for smallpox since legendary times; we know that they did practise it from at least the eleventh century A.D. Acupuncture for sciatica and other ailments seems to have been their invention. They were pioneers of massage, and the first, so far as we know, to employ blind people as masseurs. Flourishing schools of medicine existed in China A.D. 618–907, but surgical methods remained very primitive owing to their ignorance of anatomy. The myth depicted here frequently makes its appearance in Chinese art, thus showing that some importance was attached to the search for the "Philosopher's Stone."

The Scientific Extra-Dietary Product

Vitamins A B & D In Standardised Amounts

The Economic Importance of the Maintenance of Disease-Resisting Power during the Winter.

THE amount of economic waste tolerated with equanimity by past generations through lack of appreciation of the importance of prophylaxis is incalculable, and the sufferance of it is incomprehensible to the present generation.

It is now recognised that this inroad upon national efficiency has been rendered possible in the past largely on account of the depletion of the natural disease-resisting power which has been allowed to take place during the Autumn and early Winter; and it is expected that, by a practical application of recent findings of research on the rôle of vitamins in the prophylaxis of disease, a marked reduction in the incidence of influenza and other epidemics will be apparent in the coming Winter.

The daily administration of Radio-Malt—the scientifically-standardised extra-dietary product—builds up a reserve of power in the system sufficient to withstand the onslaught of infection when colds, influenza and other epidemics of the Winter months are rife.

Norman Lockyer Lecture

ON

MEDICAL RESEARCH:

THE TREE AND THE FRUIT.*

BY

SIR WALTER MORLEY FLETCHER, K.B.E., C.B., M.D., Sc.D., F.R.S.,

SECRETARY OF THE MEDICAL RESEARCH COUNCIL.

THE field of work I ask you to consider to-day is what may broadly be called medical: it is the age-long study by man of the mysteries of his own body and of its functions. If we think of the history of the mathematical, physical, and chemical sciences we see that in the successive centuries of recorded history—and here for simplicity we may take those after the Renaissance with its heritage from the Greeks—there has been a sustained progress, irregular in detail of course, but in the main a steady progress. In general, too, at each stage of advance in knowledge there has come some gain in the practical welfare or convenience of mankind. The gain has been sometimes early, sometimes late, but there has been no general and obvious dislocation in time between the stages of growth in the stem of knowledge and the harvest of its fruit as measured in new practical powers. This is manifest even if we exclude the most modern developments and consider only the three centuries from, say, the accession of Henry VIII to that of Queen Victoria, and consider the growth during that period in the powers of man to control his physical environment. In the practical arts depending on the development of these physical sciences, in all the arts of engineering and of manufacture, the world in that time had become almost transformed and was on the verge of an even more rapid progress. A continuous development of science and of its dependent arts had proceeded side by side, never far out of step at any time.

How widely different is the story of the medical sciences and of their fruits in practice! Like the physical sciences, the biological and medical sciences descend to us almost wholly from the Greeks, while our medical arts are almost purely Greek in their origin and in their ideals. After the renewal of the Greek tradition at the Renaissance we may take as a fixed point that of the publication by Vesalius of his Anatomy of the Human Body in the decade before 1550. Vesalius (of whom it is far too often forgotten that by his mother he was half an Englishman) finally broke the long tradition of appeal to the written word and opened again an era of direct observation and of the fearless record of natural facts. From his time through three and a half centuries there came an ever-widening knowledge of the structure of the animal body, accelerated and deepened by the invention of the microscope just over a century after his time. Modern inquiry into the functions of the body has followed the path opened in the early seventeenth century by Harvey, who in his demonstration of the circulation of the blood showed a perfect combination of the methods of observation with those of experiment. Throughout the seventeenth and eighteenth centuries the floods of new light coming from the long line of anatomists and physiologists that followed Vesalius and Harvey were illuminating the darkness in which physicians and surgeons seeking fresh practical powers had hitherto worked. Yet in those three centuries we cannot fail to be struck by the relative absence of medical progress having any practical significance in aid of the suffering of mankind. We may compare again the time of Henry VIII with that of the accession of Victoria, a comparison that shows such immense advance made in the mechanical arts.

Over the same period, what was the progress made in the medical arts, side by side with the steady gains in knowledge of anatomy, of physiology, and even of chemistry? The art of the surgeon had been aided by more accurate anatomical knowledge and by instruments more delicately made by new manufacturing processes, but that art was still little more than a craft of amputation; the theatre remained a mediaeval shambles of blood and pain, and the succeeding putrefaction was accepted as in its nature inevitable and irresistible. In medicine the new physiology that had developed after Harvey had given to the physician new meaning and precision to his work. At his best he followed still, as the Victorian era began, the high moral ideals and sensible practical methods of the Hippocratic school. In so far as he had discarded traditional mediaeval rubbish he was only returning to Hippocrates; but in effective power to cure or control disease hardly any progress could be claimed for the profession. Descriptions of diseases had been improved, and the arts of diagnosis. While some fashions of practice gave more palliative comfort to the patient, other fashions gave less. In sum, the advance made had been so slight that it may be expressed by what that learned medical historian Dr. Charles Singer wrote in 1921 of the Hippocratic physician: "His general armoury may be described as resembling that of the modern physician of about two generations ago." Yet the interval between the one and the other stretches over twenty-three centuries, of which the last three had been a period of scientific progress going far beyond the end-points of Greek knowledge, and included not only Harvey's transforming work, but also the introduction and use of the microscope.

No doubt you will already have thought of an event which appears to stand in obvious contradiction to the argument I have been developing—I mean the discovery of vaccination for small-pox, made by Dr. Jenner just as the nineteenth century began. But what were the circumstances of his triumphant achievement? Jenner was struck by the fact that small-pox was never suffered twice by the same person, and he was led by simple reflection and by a tireless but empirical ingenuity amounting to genius, to introduce protective vaccination, inflicting cow-pox for protective purposes as a substitute for small-pox. He knew nothing of the agents he was dealing with or their mode of action, and we know almost nothing of them to this day. To my mind this discovery provides one of the curious paradoxes of medical history. It serves to illustrate again the striking divorce between progress in biological science and progress in the medical arts to which I have been pointing. It gives the converse of what we have just been considering. Here was no new step in science, or the result of any. Jenner tried, as we may say, an ingenious practical dodge; it was not more than that, though it brought the release of whole nations from a welter of pain, and from horrid risks of lifelong disfigurement or of untimely death.

How are we to explain the remarkable relative impotence of the medical profession at the point of time I have arbitrarily chosen—the accession of Victoria? As we have noticed, the basal sciences of anatomy and physiology had made great strides, but the arts of the physician and surgeon remained much as they had been for over twenty centuries before. It is true, of course, that at that time the state of the biological sciences was far behind that of the physical sciences, having regard to the special characters of living matter and the special difficulties of its study. Organic chemistry was hardly born, bacteriology barely dreamed of, and the knowledge of cell life hardly begun. But while recognizing that, it seems plain that a great part of the sterility of practical medicine lay actually in the high development and the attractiveness of the practitioner's work as an art. His work is affected by personal and emotional relationships unknown to the practitioner in engineering and kindred arts. An essential part of the Hippocratic tradition, and indeed an obligation that every honourable practitioner must recognize, is that the physician in serving a patient must concentrate all his attention and effort upon the individual necessities of that particular case, upon its right diagnosis and due treatment; it is his duty to lay aside all speculative consideration irrelevant to the individual set of complexities presented to his judgement. The sterility arising from the inevitable failure

* Extracts from the fifth Norman Lockyer Lecture delivered before the British Science Guild on November 19th, 1929.

of the practitioner studying individual patients to make scientific progress among the complexities of living matter was clearly seen by Francis Bacon. In the dawn of the new physiology after Harvey, active practitioners like Harvey himself, and others like Glisson, Lower, Willis, Mayow, and Sydenham, in that galaxy adorning the seventeenth century, threw themselves eagerly into the work either of direct experimental inquiry or of the classification and study of collected medical observations. But after that bright age the profession in the main held aloof from experiment, and concentrated their efforts upon giving the most punctilious, and at each moment of time the best available, diagnosis and treatment of individuals. The work of individual diagnosis, based on more accurate nosology and on improving arts of observation, became more elevated as an art. But the art remained at best only the skilful attendance upon the natural curative forces of nature. Throughout the many centuries of its development it did not bring any essentially new powers of dominion over the natural processes of disease and of recovery.

Our pause at the beginning of the Victorian Age was convenient because that point marks the opening of a new epoch for the biological sciences. The first artificial synthesis had just been made of a carbon compound, urea, naturally arising in the body, and the new science of organic chemistry had just come to birth. Improvements in the methods of work with the microscope had revealed the structure of the animal cell, and it became possible to express the phenomena of disease as disorders of cell life and not as indefinite "humours" or influences mysteriously affecting the several parts of the body. As the Victorian Age advanced the microscope gave the key to the nature and life-histories of the innumerable internal parasites of man, and revealed the possibilities of man sharing with other animals or with insects an alternate interchange of parasitic agents of disease. The work of Pasteur and of Koch founded the new science of bacteriology and opened the first chapter in our direct knowledge of the swarming world of minute potential enemies or friends of man and in our powers of dominion over it.

The last four or five decades have seen a development of knowledge in the sciences contributing to medicine that has no parallel in previous history. The increase of new knowledge here and in other countries has come, indeed, so tumultuously and so rapidly as to allow no proper time for the necessary adjustments of the machinery of education, or of the traditional systems of medical education. The universities have been embarrassed to make proper provision for this rapidly expanding scientific activity and for the new branches of work that have made claims to constitute new sciences. Problems of the gravest kind in the field of medical education have come upon us so swiftly that reflection and adjustment have not been able to keep pace with them. I can illustrate this kind of difficulty best by saying that the medical student of to-day, coming to his work at the same age and giving to it the same necessary minimum of five years as his predecessor of 1900, is presented with a body of facts two or three times as great and in some subjects five times as great as that with which the former student of the same age and ability had to deal. To meet this state of affairs, full of danger as it is to the real educational welfare of the student to-day, radical changes in method and scope are obviously required and are overdue.

While this period of rapid progress is rapidly changing the traditions and methods of the medical profession, the improvements in general scientific education which have slowly occurred in the last generation are allowing the layman to take more and more an informed interest in his own relations and responsibilities to the scientific workers and to the medical practitioners and officers in whose work and welfare he is so vitally concerned.

Most laymen have observed already the great changes that the rapid growth of biological science has brought about in the conditions of the practice of the physician and of the surgeon. Easily within the memory of men now living surgery has passed from the limitations and horrors of all its previous ages and has become a merciful and delicate art. It has advanced by steady degrees until almost the whole territory of the human body has fallen within its easy mastery. This has been due to the insight, experimental patience, and humanitarian fervour of Lister, whose work is familiar to all. In this past generation, moreover, the surgeon's new powers have brought him new means of observation of the living body. Many have done pioneer work in advancing their craft, of whom Horsley, in this country, must stand as a chief example. These have used the fresh insight they have gained in their professional work to advance scientific knowledge, and have made experimental studies in laborious days systematically dedicated out of the routine and out of the remuneration of professional work. As to the art of surgery itself, it is difficult to imagine that it has any further advance to make of a major kind. Indeed, Lord Moynihan has confessed that in his view the art has almost reached its ultimate limits, undeterred by the fact that the same opinion was held by leading surgeons immediately before the advent of Lister. All present probability is on its side, however. We must believe that we have seen already the zenith of surgery in the world's history, except in so far as it must remain to deal with wounds and accidental injuries. Every step forward in medical science is a step towards the abolition of surgery.

The physician during the same period of rapid scientific progress offers a picture strikingly different from that of his fellow worker in surgery. Science by the hand of Lister gave the surgeon his new fields of work, but it was the surgeon himself who then developed his craft and pushed forward its applications. His new work gave him new knowledge and improved his own powers of diagnosis, and made him increasingly a physician himself, or the more intimate partner of the physician. But the physician's modern progress has not in the same sense depended on himself. Advances in physiology and the new sciences of biochemistry and bacteriology brought new life, of course, to every part of the physician's work and brought him also many new fields of application. But throughout this modern period the initiative as regards new methods and new remedies has steadily passed away from the physician himself to the scientific worker in the experimental laboratory.

We saw that up to quite modern days the physician followed the strict Hippocratic tradition of concentrating his powers upon the welfare of the individual patient. He relied greatly, if not chiefly, upon rest in bed and upon the *vis medicatrix naturae*. He gave drugs for the palliation of symptoms, but had few, if any, weapons for attempting the specific cure of disease. His art, an art highly developed and refined, almost expended itself upon diagnosing accurately the exact process and the end-result of the disease. I am not forgetting, of course, the exercise of his skilled functions in the right management of the patient's state of mind and in giving sympathetic and practical help to his friends—functions which in the physician's art at its best have always invested his office with a high nobility. But through the past generation it has been his medical and non-medical colleagues in the scientific laboratory who have been putting into the physician's hands new weapons of precision, in the forging of which he has played little part himself and the mode of action of which he has to take largely upon trust.

The new sciences of organic chemistry and pharmacology have been yielding many *new drugs* artificially built up in the laboratory, that have specific and measurable *actions* upon particular microbes causing disease. Of these, salvarsan may stand as a type. Chemistry and pharmacology together have also given a new meaning to some of the oldest drugs that, after immemorial use by native tribes, have been prescribed by physicians for many generations. Besides the specific remedies, such as ipecacuanha and cinchona, now provided as weapons of more precision for the physician, another important group of remedies has come into his hands. These are the so-called hormones—substances naturally produced within the body for the chemical control of particular functions. Knowledge of these is the result of the steady development during a whole generation of this branch of physiology, and in this British workers have played an active and most distinguished part.

I must not stay to dwell upon these and the innumerable other resources that have lately been added to the physician's armament against disease, among which I can do no more than mention the large group, including the vaccines and immune serums and antitoxins, coming to him from the work of the bacteriologist and immunologist. I would note in passing, however, that most of these new biological substances used by the physician are incapable of having their effective strength measured by any simple means of weighing or chemical analysis. The indirect methods necessary for measuring and standardizing them have been worked out, or are still being worked out, in what constitutes almost a special branch of research work. Without this the physician would be quite incapable of knowing either what dose to give or whether a given quantity purchased contains any given effective strength, when the life of the patient might be gravely endangered by any excess or deficiency. A piece of legislation for which scientific men have long been pressing gave us in 1925 the Therapeutic Substances Act, which now makes it possible for the physician and his patient alike to have a guarantee that what is sold to him is what it professes to be, both in potency and in purity, and the directions in which this guarantee can be given are being steadily extended as scientific work in the laboratory is enlarging the present possibilities. I must also avoid giving more than a passing reference here to those interesting and varied constituents of food called vitamins, upon the due supply of which this or that function of life is found to be dependent. Yet no chapter of biological science has greater theoretic interest than that which their discovery has opened, and no great step forward in knowledge seems likely to have a more profound influence upon the future of the medical profession and upon our powers of maintaining health and right living.

It amounts to a truism to say that progress in the practical arts of medicine in any of its branches, whether preventive or curative, only comes from the growth of accurate knowledge as it accumulates in the laboratories and studies of the various sciences. We find it a law of our state of being that where only observation can be made the growth of knowledge creeps; where experiment can be made knowledge leaps forward. The observation and description of diseases by physicians over many centuries have led, as we have seen, to almost imperceptible advance. The experimental method, only fully and widely applied in the last generation or two, has given more progress in each decade than all recorded history before. The lay public, however, who hold so vital a stake in this progress of natural knowledge, hear from time to time of a new medical discovery, but in general only after it has been handed over, so to speak, from the scientific workers to the service of practical medicine. The public see it first in the hands of the physician or the medical officer. They see little indeed of the workers from whose labours the new advance has come, or of the patient, skilled, and many-sided efforts that have contributed to its coming. They see and hear of the fruit when it has been plucked for their needs, but they see and know little enough of the tree from which it has been gathered. My chief object to-day is to show if I can how important it is that the educated public should understand the needs of this tree and the desirability of attending to its due cultivation.

We may know in the first place that as the body of accurate knowledge grows, like a tree with its stem and branches, the fruit in practical usefulness will certainly come in due course. All experience shows that. But we know also that the fruit can be expected at no regular season, and the time of its coming can hardly ever be foretold. Blossom and fruit may come upon some newborn twig, while well-established and healthy branches are slow in coming to any practical harvest.

Appetite grows by tasting, and the public, having received some of the benefits from the fruit of this tree, call loudly for more, and forget that none can be expected except by patient attention to the fruit-bearing branches and the patient cultivation of the main stems that bear them. In their bitter need suffering men and women will call out for the rapid production of some particular benefits. They will name their fruit and offer money to obtain it, though they may have long neglected the needs of the tree that alone can produce it, and while they ignore the plain fact that it can hardly ever be foretold from what part of the tree some particular fruit may come. I will drop this parable for a moment and use direct language in illustration. The ghastly menace of cancer that faces almost all of us is becoming more vividly realized since the stupid taboos that have handicapped its discussion have been dropped and since better information has been given of the amount of risk and of what it entails. Eager demand is made that the cause of cancer should be ascertained and a cure provided. The demand is natural, but in making it we must realize that new knowledge about cancer will only come and can only come as an incident springing from developments and use of our knowledge of processes deeply seated and at present hidden within the life of the animal cell. That deeper knowledge is growing, and it is growing in several directions, but no honest man would ever guess along which of them and at what stage the long-desired fruit will be gathered. It may come, as other great boons have come, by some lucky quick development, or it may be long deferred and come at last as the end-point of some extended line of work. No course of action can be supported by the wisdom of experience except that of giving every aid to the full and free development of the sciences which are here concerned. To force any undue concentration upon the immediate practical result must be unwise. Abundant experience has shown it to be sterile.

Another mistake into which the community are not seldom betrayed is to give disproportionate attention to some fruit gathered in a new practical discovery or device. It may be so obviously and highly desirable a boon that when it comes it may excite undue attention and indirectly lead to the fundamental error of forgetting the tree from which it had been gathered. Every personal honour may be rightly paid to him who plucks the ripe fruit from the branch, but it is neither to the honour of the public, nor in the long run, as it can be shown, to their advantage, that this should eclipse the credit due to those whose toil had produced that fruit-bearing branch of knowledge.

Mankind naturally will always be eager for practical progress in medical work. As we have just said, every layman now knows something of the many recent triumphs in medical science, but he knows also that these are isolated and incomplete. He sees clearly that, rapid as our progress has been within a period of years, amazingly short when compared with the preceding centuries, we are not yet in sight of anything like a victory over disease all along the line. To rest satisfied with our present achievements would indeed be a counsel of despair, and nothing could be more foolish or inhuman. Though our failures and deficiencies may be great, yet the successes already gained in the last few years, which are but as a brief moment in the history of man, should give us boundless confidence. Only the growth of scientific knowledge can bring success, and every victory must wait, as we know, upon the efforts of the unseen army of scientific workers. Practical statesmanship will turn at once to consider how that army can be aided and how it can be augmented. Three centuries ago Bacon wrote:

> "If you will have a Tree bear more fruit than it has used to do, it is not anything that you can do to the boughs, but it is the stirring of the earth and putting new mould about the roots, that must work it."

To turn this advice of his into practical effort to-day we must consider in respect of our scientific army the primary questions of recruitment, of pay, and of status.

As to recruitment, it can only be in the universities that the ablest young brains will be caught for the service. While it is true, indeed because it is true, that, as Burke said, "the State is a partnership in all science, a partnership in all art, a partnership in every virtue and in all perfection," that Government will always be wise that makes the universities strong and leaves them free. Much might be said of the modes of recruitment within the universities and of various influences that may impede it. I can only assert now that in the work of medical research there is a real shortage of able recruits. The public some-

times clamour for the removal of some dreadful evil, and expect a discovery to be produced if enough money is subscribed. They do not realize that the number of effective workers can only be increased by slow processes of recruitment and training.

If the service of research workers is to be recruited and maintained, questions of pay and status must have paramount importance. So lately as until just before the war it was the almost universal rule in this country that nobody should be paid for doing research work as such. Unless a man had private means he could only keep himself at research work by being paid to do something else, which very commonly conflicted with it. Much of it has always been done, of course, by university professors and other teachers heavily burdened with routine official duties. Salaries in academic life are in general indefensibly low. Even now professors, who may be most eminent men of world-wide reputations, are fortunate if they receive £1,200 a year, which was the low normal standard fixed by the recent Royal Commission for Oxford and Cambridge, and only a few with special administrative responsibilities receive £1,500. These are salaries which men reaching eminent success in any other walk of life would regard as an offence, and even in the academic world the headmaster of a great public school would think of them derisively. In the junior university posts the salaries are relatively even lower. A man of distinguished ability, whether in teaching or research, may count himself lucky if after an expensive training and years of toil he earns £500 a year before he reaches 30. It is true that since the war the nation has greatly increased the resources of the universities by direct grants made through the University Grants Committee, and indirectly by the funds made available for the several departments responsible for promoting research work in the three fields of agriculture, medicine, and industry respectively. Those bodies have done much to remove the discredit of starvation wages for scientific men, but it is obvious that they cannot do more than lead the way in the right direction, and not so rapidly as to bring dislocation to the university systems.

Luckily the work of scientific research is highly attractive to most eager minds, whether for its intellectual interest or for its promise of usefulness to mankind, or both, and men will always be drawn to it without the lure of high salaries. In my daily work I am continually finding men or women giving service of first-rate value to science and to the nation, yet receiving for their willing toil only a small fraction of what they might have earned in closely allied professional work or in other walks of life. I am very often reminded of what was heard during the war from a wounded man in a hospital in France. A gallant fellow, well over 50, and the chauffeur of a millionaire, was asked why he had left a secure and useful job at home to fight; he smiled through his bandages and said modestly, "I suppose my curiosity got the better of my intelligence." Very many research workers I know are entitled to make the same kind of whimsical but heroic explanation of their motives. Of these not a few face grave danger to their own lives in their laboratory work. In the long fight against yellow fever alone the names of three young English workers, Myers, Stokes, and Young, appear upon the International Roll of Honour of those who have given their lives in that campaign, in which the final victory now seems so near.

Not only fairness, but enlightened self-interest, should provoke any nation to bring the pay of competent research workers to such a level that they may hope in middle life at least to be able to bring an education as good as their own within the reach of their children. Until that is done we are in practice ensuring the sterility of those who, almost by definition, must be counted as among the most desirable begetters of our future stock.

Considerations of all these kinds have special weight in the interests of medical research in particular. Many workers in this field have a medical training, and they are exposed from the beginning to the rival and powerful attractions of medical practice. This is perfectly understandable upon any ground. The medical profession, as Sir James Paget said, "offers the most complete and constant union of those three qualities which have the greatest charm for pure and active minds—novelty, utility, and charity." The attraction towards this noble profession is strong enough without reinforcement by economic and social attractions. Consider how great these must be. Men who are making any progress at all in research work have, by that definition, exceptional ability. Given even a moderate share of character and personality—and many of them have these in rich measure—they could always, by entering practice, double or treble their income, and with good fortune become rich men. Consider the social attractions. By passing into practice they escape the uncertainties and often crushing disappointments of the research life for the immediate certainty of giving help direct to their fellow creatures. They give up the obscurity of the laboratory, with its long hours of unseen toil, for a life of active and conspicuous usefulness among their fellows, and as success comes to them this intercourse brings them friendships among powerful and interesting men and women whom they would never otherwise have met, together with every amenity and comfort of modern life and modern sport. It is at present likely also to increase greatly the chances of advance in public recognition and social rank. By passing into professional practice a man may give faithful and useful service to the community, but his service in research is inevitably, and except in the rarest instances, totally and finally abandoned.

These considerations are too seldom expressed and weighed. The problems suggested are probably soluble only in part during our own age, with its social organization and its standards of value and of reward; but it is practicable at least to set out steadily along the paths already opened towards relieving scientific workers from financial anxiety and towards a better appreciation of their primary value to the State.

I have tried to bring to your minds to-day a conception of the organic growth, with all its ramifications, of a tree of knowledge making the whole body of known biological truth. I have spoken of the largely unseen body of men upon whose efforts this growth depends. Mankind, helpless otherwise, has gained new powers over suffering and fuller life already from the fruits of this growing knowledge, and it waits anxiously for new powers again that may add to those boons. If we look at the brief period in which our present knowledge has grown, a period making an almost imperceptible point of time in the immense ages still stretching before mankind on the globe, we are encouraged to look confidently forward to a long vista of scientific progress that will bring powers of control over the processes of life of which we can hardly at present conceive. These will bring with them resultant changes in human society in a thousand ways now almost unimaginable. The value to the community of a body of men and women working to gain that new knowledge upon which the possibilities of greater happiness and works of greater mercy will spring is great. But it is not to be measured in terms only of those material fruits. The moral health of the whole community must gain from the presence within it of a band of workers whose business it is to seek out the truth and whose work from its nature can only go forward in strict obedience to the truth and by means of its pursuit and expression without fear and without favour. As the Dean of St. Paul's has lately said, in the scientific life "a keen mountain air" is breathed, and something of the tonic air of this must always serve to brace and to elevate the general community.

The true worker in natural science can owe no allegiance to any tradition however venerable, or to any master however beloved. In his work he can only serve and express the truth, and for him the truth is that which can be tested by the touchstone of an appeal to nature. He must forswear any selfish or sectional allegiance: he is "*nullius addictus jurare in verba magistri*," and that phrase of Horace has become in shortened form the familiar and honourable motto of the Royal Society. If we attempt to measure the value of the scientific life within the community we must put in the first place not the material fruits that spring from it, but the service it does to our reverence for truth and for the beauty it portrays

RIVER POLLUTION:

With Special Reference to Securing Steps which can be taken for its Prevention.*

BY

H. McLEAN WILSON, M.D., C.M., B.Sc.,

CHIEF INSPECTOR OF THE WEST RIDING RIVERS BOARD.

There must be very few medical men who have not at one time or another had their attention drawn to the polluted condition of our rivers, but there are fewer still who can remember the foulness of some of the streams in our industrial areas thirty or forty years ago, when little had been done to check their pollution.

To give some picture of the conditions of the streams at that time, I cannot do better than repeat the often quoted paragraph in the report of the Royal Commission of 1865 (pages x and xi):

"The Rivers Aire and Calder throughout their whole course are abused, obstructed, and polluted (to an extent scarcely conceivable by other than eye-witnesses) from Skipton on the Aire, from Todmorden on the Calder down to Castleford. The Rivers Aire and Calder, and their tributaries, are abused by passing into them hundreds of thousands of tons per annum of ashes, slag, and cinders from steam-boiler furnaces, ironworks, and domestic fires; by their being made a receptacle to a vast extent of broken pottery and worn-out utensils of metal, refuse brick from brickyards and old buildings, earth, stone, and clay from quarries and excavations, road scrapings, street sweepings, etc.; by spent dyewoods and other solids used in the treatment of worsteds and woollens; by hundreds of carcasses of animals, as dogs, cats, pigs, etc., which are allowed to float on the surface of the streams or putrefy on their banks; and by the flowing in, to the amount of very many million gallons per day, of water poisoned, corrupted, and clogged by refuse from mines, chemical works, dyeing, scouring, and fulling worsted and woollen stuffs, skin cleaning and tanning, slaughterhouse garbage, and the sewage of towns and houses."

This description of the Rivers Aire and Calder may be said to apply, with more or less accuracy, to many of the streams in the industrial areas, particularly in Yorkshire and Lancashire.

Incidentally, it will interest you to know that at this time the town of Wakefield poured all its sewage and trade refuse into the river without any attempt at purification, and drew its water supply from the river at a point only some three or four miles below the town. The water was purified and supplied to the town, discharged to the river as sewage without treatment, and again abstracted and circulated.

The above picture, black as it is, probably does not represent the worst condition of some of the rivers, although the Calder was then so foul and discoloured that the owner of a riverside mill wrote a complaint in water taken from the River Calder, of which a facsimile is given on page 12 of the third report of the Royal Commission of 1868. Even after this date pollution of the streams materially increased, owing to the rapid increase in population of the industrial areas, the great expansion of trade, the extension of water supplies in towns and villages, and the introduction of water-closets and water carriage of sewage.

After the reports of the Royal Commissions of 1865 and 1868 some spasmodic attempts at the purification of sewage and trade refuse were made, but the results of these did not keep pace with the increasing pollution. During this time of inaction there was one body which was in a way forced to take steps to prevent river pollution—the Thames Conservancy Board—whose duty it was to guard the London water supply. They have always been an active body, working under powers granted by special Acts of Parliament, commencing in 1857.

The passing of the Public Health Act of 1875 and the Rivers Pollution Prevention Act, 1876, showed that the public conscience was becoming stirred by the recognition of the foul condition of the rivers, and during the following years some further attempts were made towards improvement, but these amounted to very little. In 1889, when the county councils and the county boroughs were set up, some of them turned their attention to the improvement of the rivers in their areas, and as one result three joint committees were formed. These were statutory bodies constituted under Section 14 of the Local Government Act, 1888, with the sole duty of administering the Rivers Pollution Prevention Act: the Mersey and Irwell Joint Committee and the Ribble Joint Committee in Lancashire, and a joint committee (now the Rivers Board) for the West Riding of Yorkshire.

These bodies at once began to take action, and coincident with this one or two of the county councils turned their attention specially to the matter—for example, Durham under Dr. Eustace Hill, Derby under Dr. Barwise, and Warwick under Dr. Bostock Hill.

The joint committees and county councils were given no fresh powers for dealing with river pollution; they had to administer the general Rivers Pollution Prevention Act, which could have been brought into use by any sanitary authority. Later, however, special Acts were obtained by the Mersey and Irwell Joint Committee (Mersey and Irwell Joint Committee Act, 1892), and by the West Riding of Yorkshire Rivers Board (West Riding of Yorkshire Rivers Act, 1894), but these added very little to the powers given by the general Act of 1876.

So far as the general sanitary authorities and most of the county councils were concerned little or no use was made of their powers. The reasons for this inaction are not far to seek, at least in the case of sanitary authorities—other than the county councils. They were themselves, for the most part, great offenders, and could not take action against other offenders without drawing attention to their own sins. The inaction of many of the county councils is not so easily explained. Probably the general reason was that their powers were new, their medical officers had a number of new duties placed upon them, and were not provided with the special staffs required to deal with river pollution. They had, in fact, duties of more immediate importance, such as water supplies, removal of crying sanitary nuisances, and duties in connexion with epidemics.

It may be inquired what has been the result of the action of the joint committees and those county councils which have taken up the question of prevention of river pollution seriously. I can, of course, speak with some authority mainly of the rivers in the West Riding.

The condition of the Rivers Aire and Calder, which was so vividly described in the Royal Commission Report of 1865, is now vastly different. Even thirty years ago the River Aire at Leeds was so foul and septic in its course through the city that frequent complaints were received of the injury to health of workpeople in the factories on the river banks. In dry summers the nuisance was felt in the streets of the city, even as far as the town hall, half a mile from the river. This was the condition within the city of Leeds, and the state of matters was worse lower down, after the Leeds sewage and trade refuse, with very little treatment, had been discharged into the river. For example, from Castleford, where the river is churned up by passing over a considerable weir, complaints were frequent, strong, and bitter.

The condition of the River Calder was very similar. There is a fairly large weir across the river at Wakefield, just above Kirkgate Bridge (which is well known to motorists by its Chantry Chapel), and here the smells from the water, broken up by passing over the weir, were extremely offensive; and particularly in times of flood, after a dry spell, the water was so thick with solids washed down from the bed of the river that it might be said to roll rather than flow over the weir. The Aire and Calder Navigation Company, in dredging both rivers for the passage of their boats, had to remove thousands of tons of cinders and other solid refuse.

These rivers are now in a very different condition; there arise no offensive smells from them; their waters are now only slightly discoloured, and the amount of suspended matters they ordinarily carry is less than that of a natural stream in times of flood. These improvements have been carried out in spite of steadily increasing discharges of sewage and trade refuse. The population of the two

* Read in opening a discussion in the Section of Public Health at the Annual Meeting of the British Medical Association, Manchester, 1929.

valleys has increased enormously, with an accompanying increase of sewage; there has also been a great increase in the volume of sewage owing to the spread of the water carriage system of drainage and the extension of sewers, and the amount of trade refuse has greatly increased. Had no attention been paid to the prevention of pollution, the condition of the rivers that would have resulted from all this vast increase of sewage and trade refuse which has been poured into them can scarcely be realized. One is tempted to wish that for a month all treatment of sewage and trade refuse in these two valleys could be brought to a standstill, so that the inhabitants could more fully understand what the work of the Rivers Board has meant to them.

The burden these rivers have to bear in the way of sewage, sewage works effluents, and trade refuse is very great. The Calder below Wakefield, with a dry weather flow of some 100 million gallons a day, has received over 30 million gallons of these liquids; the Aire below Leeds, with a daily dry weather flow rather less in amount, has received about 50 million gallons.

It has also to be noticed that the sewage works of many of the towns are far from complete, although their extension is now in progress. When these various works are brought into full use, and the trade refuse discharges are connected up, as many of them will be in the near future, the improvement in the rivers will be still more marked. There will, however, always remain considerable pollution caused by the discharges from sewers in wet weather. Pollutions by storm water have, indeed, during recent years become more serious owing to the rapid run-off of rainfall from impervious road surfaces, and the Ministry of Health regulations relating to treatment of storm water stand in need of revision, if this form of pollution is to be lessened.

In addition to the work done by the Rivers Board in lessening pollution of what may be called the industrial rivers, like the Aire and Calder, their attention has been constantly directed to the prevention of pollution of the cleaner and more natural streams, such as the Wharfe and the Nidd, rivers which are full of fish. In these valleys there is now no considerable village unprovided with sewage purification works; even small hamlets and detached farmhouses have made some provision for preventing their sewage reaching the streams. As a consequence, these streams have been kept from deteriorating, and their waters are purer than those of some of the rivers which form the source of public water supplies. The water of the Wharfe, for example, below the towns of Ilkley and Otley is purer than the water of the Thames at Hampton.

These are some of the results of thirty-five years of the work of the Rivers Board, although it must be acknowledged that a great deal still remains to be done; it must, however, be remembered that during this thirty-five years there were six or eight years' inactivity because of the war and its effects. All this work may be said to have been done under the general Rivers Pollution Prevention Act of 1876, and the provisions of that Act could have been set in motion by any sanitary authority.

I wish particularly to draw your attention to this statement: any sanitary authority during the last fifty years could have taken the same action to prevent pollution of streams within its districts as that taken by the rivers boards, and could do so to-day, because the legal powers of the rivers boards are no greater than those which every sanitary authority and every county council possesses under the 1876 Act. The only difference is that the jurisdiction of the rivers boards extends over a greater area.

The reasons for the inaction of the sanitary authorities have already been briefly mentioned. There is, under present conditions, little prospect that this inaction will come to an end. What is the remedy? This has been pointed out by commission after commission. I need only direct your attention to the third report of the Royal Commission of 1898, page xxvii, and to the recent report of the Advisory Committee on River Pollution, both of which advise very clearly that joint committees or rivers boards should be set up with powers to deal with the question of river pollution.

Such a board should have under its jurisdiction the whole of a river and its tributaries; it should have an area large enough to justify the employment of its own special staff of inspectors and chemists, and the area should not be so large as to prevent the board's chief officers from becoming familiar with all sources of pollution.

The mode of establishing such a board or joint committee is set out in the report of the advisory committee referred to:

> "It is therefore possible under the law as it stands at present for the Minister, on the application of any one of the county councils or county borough councils through whose jurisdiction a river passes to set up a rivers board to control the whole length of the river, including its tributaries, so far as it is subject to the Rivers Pollution Prevention Acts."

To this procedure I would earnestly direct attention. The Ministry of Health has already sent to all county authorities the report of the advisory committee, and it now lies with these authorities to make the necessary application to the Ministry of Health. The influence of the British Medical Association, and such action as it may take, will go a long way towards bringing about the desired effect.

The cost of such a joint committee need not be great. In the West Riding it amounts to one-seventh of a penny in the pound on the rateable value, and this cost is diminishing, as, owing to the present facilities of travelling, the number of inspectors required has been lessened. The Rivers Board staff consists of a chief inspector, his deputy, a number of district inspectors, and legal, laboratory, and clerical staffs, and these would be necessary for the proper equipment of any rivers board, their numbers, of course, depending upon the area and the number of pollutions to be supervised. Such a board, devoting its attention entirely to the question of river pollution, and with a staff trained for the purpose, is, in my view, necessary before river pollution receives the attention it so urgently needs.

It may not be a legal requirement that a prosecuting authority should suggest practicable means for the purification of a polluting liquid, but in practice the Ministry of Health, whose consent to legal proceedings against a trader is necessary, must be persuaded that such means do exist, and it generally falls to the prosecuting authority to prove this. It is, in fact, my own experience that in dealing with new kinds of pollution many researches and experiments must be undertaken, and the experience of others, both at home and abroad, ascertained, before any application to the Ministry of Health can be made with reasonable prospect of success.

A rivers board has for its first duty action compelling offenders to cease polluting the streams, but I would not have you think that its duties end there; in fact, this is the smaller part of its work. Its officers should be in constant touch with the officials of the sanitary authorities and with traders who have waste waters to dispose of, and should be able to suggest to them the best means to be adopted for the prevention of pollution. In this way a board is able to assist those whom it has power to compel, and the result in numberless cases has led to notable economies, particularly in the case of traders. In this way, and also by insisting that polluted waters are rendered fit for ordinary use, the establishment of a rivers board may be looked upon as economical rather than expensive.

What is the alternative to the establishment of such boards? Either, as in the past, the sanitary authorities will remain inactive, and pollution will go on as before, or, stirred by complaints of new pollutions, spasmodic action will be taken by an authority here and there—action taken without the assistance of any skilled staff, and without the authority being able to assist the manufacturer to put his house in order. This is a most regrettable position for an authority to be in, for every one of them is anxious to attract to its district the establishment of new factories, with their rateable value and their employment of the working classes; and, on the other hand, the traders are generally desirous of carrying out their processes without harming their neighbours, provided that they have confidence in the means to be adopted.

The matter is urgent. Complaints are being made from all over the country, not only of the condition of streams which are recognized as passing through industrial areas, but of some of our beautiful fishing streams in rural country, where until recently practically no pollution existed. These new trade pollutions are of immensely greater magnitude than the old. Formerly there were numberless comparatively small factories with discharges varying between twenty and thirty thousand gallons a day of dirty water. Now, from beet sugar factories, artificial silk factories, and large dairies, the volume of foul water may amount to millions of gallons from one factory in a day. Thus one such large factory may entirely change the character of a formerly clear and unpolluted stream, and I am sure that many of you are aware of this having happened. If such pollutions are not promptly and properly dealt with the deterioration of our streams is certain.

This is a serious matter from many aspects, but especially serious in view of our increasing industries and population, and the difficulty of obtaining sufficient water supplies.

The question of fishing deserves consideration, for instances are known where, by the establishment of one of these modern factories, fish have been utterly destroyed and gathered up literally in cart-loads; and the value of fisheries is very great, although rapidly lessening because of pollution. The pleasure given to countless thousands by the fishing available in our clean streams and their enjoyment of the amenities of our country valleys are also to be considered. Perhaps none but those who have lived in our industrial valleys near a stream fouled by sewage and trade refuse can fully appreciate the delight afforded by a clear running stream in beautiful surroundings. To improve the condition of streams which are already polluted, and to prevent the pollution of these clean streams, is certainly well worth a great effort.

I have said that much good work could be done under the existing Acts of Parliament, but there is no doubt that in many respects these require amendment. This has been pointed out by various commissions, and will no doubt be dealt with by the advisory committee now sitting; but there is no reason to wait for an alteration in the law before putting into force the present powers. There is, however, one point where, possibly by agreement, an important change in the law would be of great value. The powers and rights of sanitary authorities and traders respectively, with regard to the admission of trade refuse into sewers, are by no means definite, and the practice in this matter varies from town to town. Some towns admit to their sewers, and deal with at their sewage works, all trade refuse without terms and without payment. Some towns absolutely refuse to admit any trade refuse into their sewers, and there are many modifications between these two extremes.

To my mind, in industrial areas, no satisfactory purification of the streams will be effected until trade refuse is dealt with along with the sewage of the towns. This, of course, ought only to be on terms of preliminary treatment of the trade refuse, or payment by the traders, or both. The matter has been dealt with by the Royal Commission of 1898 (see third report, paras. 22, 23, and 24, and the ninth report, para. 10). As the Royal Commission has pointed out, it is obviously inadvisable that the law should give the manufacturer "the absolute right" to discharge his refuse into the public sewer. This is evident on considering the case of one of the new large factories, already referred to, established in a small town or country village, where the amount of trade refuse may be a hundred times the volume of the domestic sewage of the place. In any change of the law provision would have to be made for dealing with such cases, but this is no time to discuss details.

I need only refer to one other desirable alteration in the law. Power should be given to some higher authority to decide between the authorities of adjacent districts when they propose, each of them, to set up their own sewage works. It is a scandal to see the countryside dotted with separate sewage works, where these could readily and more economically have been centralized. Without additional legal powers it is nearly impossible to overcome the jealousies between many of these local authorities, although in numerous cases, soon after they have constructed separate sewage works, they wish the policy of combining and centralizing had been followed.

In conclusion, the measures for dealing properly with river pollution are not likely to be thoroughly undertaken until special boards are set up for the purpose. Such boards could be set up, and do good work, under the existing laws. The laws need amending, especially that relating to the admission of trade refuse into public sewers. Every county council and council of a county borough should consider the condition of the rivers and streams within its district, and where pollution exists should represent to the Ministry of Health the desirability of constituting a rivers board.

THE SIGNIFICANCE OF VITREOUS OPACITIES.*

BY

T. L. DE COURCY, M.D.,

HONORARY OPHTHALMIC SURGEON, EYE AND EAR INFIRMARY, LIVERPOOL, AND SOUTHPORT GENERAL INFIRMARY.

To assess the true significance of vitreous opacities in every patient is an impossibility, but certain factors help us to come to a decision as to their importance or otherwise in most cases.

In the first place it is essential to recall the embryology of the vitreous. Those of you who were present at the 1927 meeting of the Ophthalmological Society of the United Kingdom will have heard Miss Ida Mann's admirable paper on the development of the vitreous; if not, you have probably read the paper. Miss Mann[1] there states that from the union of the mass of fibrils derived from lens and retina with those from the walls of the hyaloid artery the primary vitreous is formed in the foetus. She goes on to describe the formation of vessels in this vitreous and their subsequent atrophy, forming near the retina an avascular area named the secondary vitreous. After the third month of foetal life fibrils from the growing margin of the cup help to form the tertiary vitreous with a condensation of fibrils from the hyaloid membrane separating the secondary from the tertiary fibres.

As development continues condensation takes place, so that the adult vitreous consists of the primary portion filling the retrolental space and passing along the canal of Cloquet to the optic disc; the secondary vitreous extending from the boundaries of the primary to the internal limiting membrane, and the tertiary forming the suspensory ligament of the lens. The point is emphasized that the vitreous body is not enclosed by a structureless hyaloid membrane, being separated from the retina only by the internal limiting membrane.

The slit-lamp has added much to our knowledge of the structure of the adult vitreous. With a dilated pupil the retrolental space can be made out, and behind it the anterior portion of the vitreous, with its delicate waving fibrils and nodules. Even a portion of the canal of Cloquet can be distinguished, and separate moving bodies in certain cases, pigmented or otherwise. The vitreous is seen to differ in appearance with the individual, and may show a disorganization of what we consider the normal. The rapidity of the movements of the fibrils, their density, or their altered appearance to that of cotton-wool fibres are examples of what is meant. Bedell[2] states that pathological changes in the vitreous depend on changes in the framework and pigmentation, and that framework characteristics are marked by absorption of some fibres and the massing of others. He describes floaters as appearing like fine white lines, isolated fibres, single short threads, as a skein or tangle of cotton-wool, as cotton-like masses, white dots, heavy dust, and as snowflakes. Blood appears as roundish clumps, ovals, granules, and large masses.

With the contact glass much more of the vitreous can be seen; but of this I have no personal experience.

The investigation of the chemical and physical properties of the vitreous has recently been fully undertaken by some

* Read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Manchester, 1929.

of our own scientists, and to Mr. Duke-Elder we are indebted for his valuable work on the subject. He describes the vitreous as a colloid gel lying in the meshes of a scaffolding composed of a network of long interlacing fibres. This liquid is practically identical in every way chemically with the aqueous, though more viscid. Protein is contained in considerable amount; immune bodies, fat, cholesterin, urea, sugar, salt, calcium, and potassium are all present. It differs from the aqueous by containing, in addition, a muco-protein and a residual protein whose chemical nature has not yet been determined. In Duke-Elder's own words, "It seems that these two proteins are secreted by the surrounding ectoderm (mainly the retina) and that the common intraocular fluid (a dialysate of the capillary blood) percolates them and swells them up to form a gel."

Continuing his deductions, Duke-Elder[2] argues that any alteration in the metabolism suffices to make the gel fluid with the separation of its protein basis in the form of strands, films, or strings, and this change is due to some internal variation in the economy of the vitreous. What these variations are cannot yet be fully established—probably either a change of salt content or a failure in the efficiency of an autoxidation system. Probably the largest number of vitreous opacities we see in seemingly healthy eyes are from this cause. The haemorrhages and exudates in cases such as irido-cyclitis take place largely from the retinal vessels or the ciliary body, the endothelial cells in the media or intima of the capillary walls being affected by certain toxins circulating in the blood. The function of the cells being impaired a leakage takes place—the leakage taking the form of fibrinous exudates or haemorrhages.

With these facts before us—namely, the changes which take place in the development of the eye in foetal life and after birth, the condensation of the vitreous, and the disappearance of the embryonic elements, the structure and chemical constitution of the vitreous, and the function of the capillaries in the retina—we are in a position to suggest a classification of the most usual vitreous opacities as due to (1) changes in the condition of the capillary walls; (2) changes in the condition of the blood; (3) changes in the vitreous—congenital, traumatic, and mechanical.

1. Changes in the capillary walls, such as thickening, are a fruitful source of vitreous opacities. In arteriosclerosis it is almost the exception not to find floaters, which assume many forms. It may be taken for granted that in most people over middle age capillary changes to a greater or lesser degree are found, and a careful examination of the vitreous reveals in many cases the results of the exudates from the capillaries in the form of floaters.

2. Changes in the condition of the blood are responsible for the largest number of vitreous opacities. Whatever the toxin may be, the nutrition of the endothelial cells of the capillaries is interfered with, and leakage may occur. The grosser opacities found in focal infections giving rise to irido-cyclitis are due to this, but many focal infections may show no other effect in the eye than that of vitreous opacities. As an example of this, a patient examined a few weeks ago showed heavy floaters in the right eye as a result of a very severe irido-cyclitis some three years previously, but the left eye, which had never been seemingly affected, also showed numerous opacities to a lesser degree. To my mind this (and several other cases investigated) would prove that the toxin in the blood may not be sufficiently potent to produce external signs and yet be powerful enough to produce this leakage into the vitreous—a point I have never seen noted. In the more serious systemic diseases one expects and finds such leakage—for example, the numerous dust-like opacities often found in syphilis. In a mild chronic cyclitis which produces little more than an irritable eye I have found floaters in many cases, but the frequency with which they are found in the seemingly healthy eye gives much more room for speculation as to their cause. In the routine examination of a young woman of 25, floaters were found in both eyes, the fundi being normal. I found that she had been feeding her baby for six or seven months, and was feeling run down. A blood change through excessive lactation is a possibility in this case, and an examination of the recently delivered women in the maternity ward of my local hospital failed to show any evidence that any change took place during early lactation. Floaters have been observed in blood diseases showing glandular enlargement, and it is more than possible that the ductless glands also give rise to the appearance of vitreous opacities. A woman whose hair was falling off, whose skin was dry, and who showed other evidence of thyroid interference, gave a beautiful appearance of asteroid bodies in her vitreous. Two years afterwards I examined her again, when the thyroid symptoms had disappeared, as had also the asteroid bodies to a large extent. Another case illustrates the same point. A patient examined two years ago then showed normal fundi and media with low hypermetropic astigmatism. When seen again recently the hypermetropia had increased 1 D, and in the vitreous of each eye were numerous fine floaters, though the fundi were normal. Uncorrected distance vision had fallen from 6/6 to 6/12 in each eye, but the corrected vision was 6/5. The patient said he was run down, his digestion was uncertain, and that his doctor said his heart muscles were weak—all since an attack of influenza a few months previously. These symptoms all point to a toxic condition of the blood with the manifestation in the vitreous of exudates. In several cases of iritis of one eye vitreous opacities were clearly evident in the other, and many similar cases could be cited. The class of vitreous opacities where the protein base of the vitreous separates out owing to deficiency in oxidation or change of salt content, being affected by the changed capillary blood, also indirectly comes under this heading, and most cases of myopic opacities, but reference will be made to these later.

3. (*a*) Congenital remnants. In the condensation of the fibrils it is likely that some residue is separated out, and it is quite possible that some of the single, almost colourless strands we often find in the vitreous are from this cause. Miss Mann is of opinion that condensation of the fibrils continues during life, and in certain cases the effects of this are seen as floaters; the possibility of this change being to some degree pathological must be considered. Also the single dark speck not infrequently seen in children is possibly of congenital origin. Floating worm-like remains of the hyaloid artery are not uncommon, and the attached persistent hyaloid is often seen. These vascular remains are found more frequently in the extreme anterior or extreme posterior part of the vitreous.

(*b*) Trauma, when not sufficient to cause haemorrhage, may still upset the delicate mechanism of the vitreous gel, and a very small degree of trauma may cause separation of the protein base and liquefy the vitreous, producing floaters.

(*c*) Mechanical obstruction, as in venous thrombosis, produces haemorrhages from the venules (not the capillaries) with the unabsorbed residue left as vitreous opacities. It is an interesting fact that retinal haemorrhages occur at birth in from 15 to 20 per cent. of all confinements. These haemorrhages are purely mechanical, and fortunately clear up in the large majority of cases, but we find occasionally in children unexplainable vitreous opacities which may be due to this source.

As some slight guide to the frequency with which vitreous opacities occur I made a careful examination of them in a series of patients in my private practice. I took 100 consecutive patients and included all except those whose fundi could not be examined, either through extensive lens changes or corneal disease. In this series vitreous opacities occurred to a greater or lesser extent in 37 per cent. of the cases. I then took a series of the next 100, and in this the percentage was, curiously enough, exactly similar. Notes were made as to the sex, age, type of refraction, lens changes, and fundus abnormalities, and though from a statistical point of view the result may be of little value, many points of interest came to light. These two series of cases contained a comparatively small number of children, as it was not the holiday season, but the number of cases showing opacities is rather more than one would expect, and it is, if anything, underestimated. In many cases the opacities were of the light, almost colourless, cotton-wool variety, in some cases one or two small specks, in others dust-like opacities, but in the majority of older people, at any rate, a mixed variety.

In these 200 cases there were 33 examples of myopia above 1D, and in 23 of them floaters were found. Only 6 had fundus disease apart from arterio-sclerosis, while in the last-named condition floaters were almost universally present.

In the first place, as to the method of examination—the ophthalmoscope was chiefly employed, the slit-lamp being used only in a few special cases. The luminous ophthalmoscope used in these examinations for vitreous opacities contained two lenses which could be moved coaxially to the path of light and between them an achromatic lens which could be moved up and down along the axis of the instrument by means of a collar. The two lenses first mentioned could be moved out of position, thus allowing the light to fall incident on the achromatic lens. This produced a slightly divergent beam, effecting the result of a plane retinoscopy mirror, and this was found to be the most favourable position for detecting the opacities. Contrary to what was formerly taught, it was found that the greatest possible light that could be reflected on the vitreous made the opacities more obvious. A red-free filter was also available, but only in certain cases was it of any value. Quick up and down movements of the eyeball were made by the patient, and with light focused on the reflection of the optic disc and by adding *plus* lenses of from +5 to +20 little difficulty was experienced, even with an unilated pupil, in detecting the floaters if the method was carried out thoroughly. In the majority of cases where the opacities were very faint they were detected in the posterior part of the vitreous. Whether the position in the vitreous of the opacities has any special significance I have failed to determine, though it is stated that when using the slit-lamp the early appearance of the cells and deposits in the retrolental space is a feature of considerable significance in the detection of early corneal inflammation.

Should it be wished to measure the depth of the opacities with the ophthalmoscope—and I should judge that it is only necessary when we find a large single opacity more or less fixed in position—it can be done by determining the difference in dioptres between the lens by which the opacities are clearly seen and the lens by which the fundus is visible: 1 mm. corresponds to a different refraction of 3D, and so if an opacity is best seen by +8D and fundus with −4D, 12 ÷ 3 = 4 mm. in front of the retina.

Few of the patients examined in whom floaters were found complained of "black spots" until asked directly about them. In several whose chief complaint was the inconvenience caused by spots no vitreous opacities were detected. In some of these cases, where none were found, the slit-lamp showed lens changes almost unrecognizable by the ophthalmoscope. Floaters may be present in large numbers, and may give rise to practically no subjective symptoms, and yet a solitary floater may cause much annoyance. After an illness, or during the stress of heavy office work, or when glasses need to be changed, the floaters appear to cause the patient much trouble. The liver theory that is popular among our patients may have some substratum of truth.

Incidentally, among myopes the subjective symptoms are the most marked, as the uncorrected vision is indistinct and the opacities better projected on the hazy background. The reason why myopic eyes should be more subject to floaters is not fully established, just as the reason for the elongation of the eye is theoretical. Possibly v. Graefe's theory that the elongation is due to an inflammatory process in the choroid and sclera is the most sound, the sclera becoming softer and more yielding. This mild inflammation would give rise to exudates and haemorrhages and hence to opacities. Possibly the changes are so slight as not to be detected with the ophthalmoscope, and so opacities are found in seemingly healthy myopic eyes. In other cases of myopia elongation may take place from congenital deficiency of the ciliary muscle retarding the outflow from the eye and so increasing intraocular tension. This may give rise to internal changes in the vitreous and cause separation of the protein base and ultimately opacities.

In the periodic examination of young myopes, where we find the myopia increasing in a rapid manner we are often in difficulty as to whether to advise withdrawal from school for a period as a means of checking the myopia. Should we find a normal myopic fundus but the appearance of floaters never before noted, or an increase where they have previously been present, it is a decided point in influencing us to advise rest for the eyes.

As previously stated, in cases of marked arterio-sclerosis floaters are generally present as a result of changes in the capillary walls, and their absence is a more favourable sign for prognosis; also, opacities are frequent in eyes with early lens changes, and possibly the cause of the two conditions is similar whatever it may turn out to be. A record of the motility of the opacities before the advancing lens changes obscure the view may be helpful with a view to subsequent operation, or the rate of movement of the floaters may give us some idea of the fluidity of the vitreous.

The size, shape, number, and rate of motility of vitreous opacities vary enormously with the eye and the conditions causing them, but in very few cases do they interfere seriously with vision. I have seen a fixed opacity causing a central scotoma owing to its position, but fortunately this is rare.

I have purposely avoided much mention of large haemorrhages and exudates, new blood vessels in the vitreous, vitreous detachments, congenital abnormalities such as persistent hyaloid artery, and suchlike, as their significance is obvious. In retinal detachments the presence of vitreous opacities would tend to point to a serous origin of the condition rather than to a neoplasm.

One type of vitreous opacities, however, must be described in some detail as their detection is at any rate of academic interest, and probably more than this. I refer to the asteroid bodies first described by Benson—my first teacher in ophthalmology—in 1893. These bodies, when seen by the ophthalmoscope, vary in appearance from white star-like globules, lazily and gently floating in their firmament, changing their position with the movement of the eye, but returning to somewhat the same area, to the snowball variety, more massive and fewer in number, or the more quickly moving and less luminous type. They are easily detected, even with the non-luminous ophthalmoscope, by the indirect method, and it has been noticed that when focused against the whitish background of the disc they often lose their luminosity.

The occurrence of these bodies has been recorded in the literature very infrequently from the time of Benson's case till the last few years, though it is more than probable that they were confounded with cases of synchysis scintillans, from which they differ both in appearance and in origin. The glittering shower of coloured crystals of cholesterin falling rapidly to the lower part of the vitreous is entirely different from the appearances above described. On seeing my first case some six or seven years ago I discovered a description of the condition,[4] and the statement that only about twenty such cases had been recorded. Since then I have seen nine or ten cases, and, curiously enough, have not seen one case of synchysis scintillans in my own practice since that time. One must conclude that the asteroid type is much more common than is generally supposed, and much more frequently met with than the cholesterin type.

Various theories have been put forward as to the origin of the asteroid bodies. Among such theories are: that they are an exudate secondary to tuberculous cyclitis; that they depend on arterio-sclerosis in association with an altered blood condition; that they are formed through deficiency of oxygen in the vitreous; that they are due to disease of the ductless glands through an altered condition of the blood; together with others less likely. The constitution of the bodies has been investigated, and it has been proved that they consist chiefly of calcium soap, calcium carbonate, and a certain amount of fatty or lipoid substance in combination of various grades of stability.

Among my own cases were some old people with marked evidence of arterio-sclerosis; a woman of middle age, in whom the asteroids had cleared up almost completely when seen again after three years, as had the symptoms of thyroidism previously present; a woman aged 35, whose doctor gave her a clean bill of health; and a man of 60, who said that for thirty years he had had chronic indigestion. These cases cannot all have a similar origin, but a

toxic factor in the blood associated with an altered chemical condition of the vitreous may give rise to their formation. Vision appears to be little affected by these bodies *per se*.

Our knowledge is not sufficiently advanced to give a satisfactory explanation as to why some vitreous opacities are completely absorbed and why some remain easy of recognition by the ophthalmoscope and slit-lamp. So long as the toxic state of the blood or the weakened condition of the capillary walls continues the floaters are likely to persist, though the removal of the cause does not in every instance clear the vitreous.

Absorption can be hastened by medicinal and local treatment. Iodides internally and diomine externally appear to be the most efficient drugs, though many other drugs are used. Aspiration of the vitreous is helpful where the floaters are so heavy as to interfere seriously with vision, but I have no personal experience of this method of treatment. The detection and removal of the focal source of infection is, of course, indicated.

To sum up, we find that vitreous opacities must be considered in the light of the surrounding picture—the shape of the eye; the condition of the fundus, of the vessels, and of the lens; the age of the patient and his general physical condition, past and present. The occurrence of opacities in the vitreous is comparatively rare in children, but frequent in middle life and old age. Their presence is more frequent than we are led to suppose, and in the aged they are a usual occurrence when arteriosclerosis is present. In myopia of even moderate degree floaters are frequently observed in adults, and in young people showing progressive myopia their appearance must not be disregarded. In early cataract the occurrence of vitreous opacities is common, and it is quite possible that the cause of these may be the same as that which leads to the lens changes.

Much the most usual cause of vitreous opacities is an altered condition of the blood due to general or local toxic causes; they may, indeed, be the only sign of focal infection in the eye. The glandular system, and even the ductless glands, may be a factor in their causation.

Apart from those of developmental origin, all vitreous opacities have some special significance, though their origin, as in the case of focal infection, may be difficult to discover.

The cases in which vitreous opacities interfere seriously with vision are few, and the subjective symptoms caused have little proportion to the number of vitreous opacities present.

The careful noting of the presence of vitreous opacities and their rate of mobility will have its reward in the future treatment of our patients, is often an aid to prognosis, and may aid us as to the expectation of fluid *vitreous in cataract operations*.

This very inadequate review of a subject which has hardly had its proper place in the literature of ophthalmology may lead to its study by others; it is a subject of which much has yet to be learnt, but which, with modern and more adequate methods of examination of both the vitreous and the general condition of the patient, is capable of much exploration.

A CASE OF EMBOLISM AT THE BIFURCATION OF THE ABDOMINAL AORTA TREATED BY OPERATION.

BY

J. LE FLEMING BURROW, M.B., CH.B.ED., M.R.C.P.LOND.,

HONORARY PHYSICIAN, WITH CHARGE OF OUT-PATIENTS, TO THE GENERAL INFIRMARY, LEEDS;

AND

E. R. FLINT, F.R.C.S.ENG.,

SENIOR HONORARY ASSISTANT SURGEON TO THE GENERAL INFIRMARY, LEEDS.

THE following case is reported because it presents several points of interest. The condition is a very rare one; our investigation of the literature shows that less than a dozen cases have been reported—mostly from Sweden—and all have ended fatally. Heart disease has been present in all. This case is, we believe, the first of its kind to be published in this country. Embolectomy has been successfully performed for emboli in other large vessels; Jefferson[1] reports some 28 successes; one of the chief factors in this respect seems to be the time of operation—any time up to twelve or fifteen hours gives a fair prospect of success. Our patient was not operated on until thirty-six hours after the onset. Circulation was, however, successfully re-established—this is the second reported case only in which the circulation has been re-established after so long an interval. As the patient died twenty-four hours after the operation it is impossible to be sure that the recovery in the circulation would have been permanent, but the post-mortem appearances were such as to suggest that at even so long an interval after the onset it is worth while attempting to free the vessel of clot. The multiplicity of emboli in this case, and in many others reported, has been the determining factor in producing an unsuccessful result. The clinical record is as follows.

A married woman, aged 62, was seen by one of us (J. le F. B.) on December 23th, 1927, and admitted to the Leeds General Infirmary the same morning. The history was as follows. The patient had not been well for a few weeks; she was easily tired and out of sorts. There was a history of rheumatism in her youth, but she had enjoyed fairly good health on the whole up to a few weeks prior to admission to hospital. The day before she was seen she was seized with a most sudden and severe pain in the left iliac region, which was promptly followed by loss of power in both legs. The pain continued to be most severe to the right and left sides below the umbilicus, but settled down chiefly in the left iliac region a few hours before she was seen. She complained of complete loss of power and sensation in both legs. She was unable to pass her water.

When seen by one of us (J. le F. B.) on the morning of admission to hospital there was a complete flaccid paralysis of both lower extremities, with loss of reflexes and all sensation. There was no pulsation below the bifurcation of the abdominal aorta, and both legs were cold and pale. Short mitral presystolic and systolic murmurs were audible, and a diagnosis of thrombosis of the abdominal aorta was made on the spot. It was recognized that the patient was very gravely ill, and her immediate removal to hospital was urged. Thereafter she was under our joint care, and as no improvement was noted within twenty-four hours it was decided to make an attempt to remove the clot from the aorta. The operation was decided upon in the forenoon of the day after admission. The following are the details of the operation.

The abdomen was opened by an incision about 4½ inches long to the left of the middle line and the aorta exposed. There was no pulsation beyond about one inch proximal to the bifurcation. The aorta was controlled some 2½ inches above the site of the clot by the fingers of the assistant and by a light rubber clamp, and then opened for 1½ inches longitudinally. Much dark clot extruded and was extracted from the aorta and both common iliac vessels; the clots were some six inches in length. The aorta was stitched with interrupted through-and-through sutures of fine silk in one layer. On releasing the aorta pulsation returned at once in all the iliac vessels, and could be felt easily in both popliteals. There was no leakage from the suture line or the stitch holes. The abdomen was closed in the usual way without drainage.

The appearance of the abdominal wound was very striking; in the upper half there was the usual bleeding after making the incision; the lower half had a greyish-green colour and bled not at all. After the aorta had been freed of the clot, sutured, and released, the lower half of the abdominal wound began to bleed freely and assumed the normal ruddy colour.

It is interesting to note that, though the operation was not performed for some thirty-six hours after the sudden blocking of the aorta, when both limbs had completely lost all power of movement, and were cold and had assumed the purplish mottling seen post mortem, yet the circulation was apparently completely restored and power in the limbs was returning after the clot was removed.

At the subsequent post-mortem examination all the veins of the legs were patent and showed no evidence of clotting; in view of this and the other post-mortem findings, it seems reasonable to assume that death was due to clotting in the cerebral vessels, the

clot being derived from the heart, and that death was not due in any way to the derangement of the circulation in the lower extremities, or its sudden return. The embolus was approached by the abdomen rather than retrogradely by way of the femoral vessels *because the physical condition of the patient was satisfactory* for the abdominal route.

Subsequent Progress.—The patient stood the operation well, and pulsation was evident in both popliteal arteries and the posterior tibials the evening after the operation. She seemed very toxæmic, and the pulse was quick, though it slowed down to about 80 per minute the same evening. She died rather suddenly at 9.20 a.m. the following day, from a simple failure of respiration and heart, without any further incident such as might point to pulmonary emboli or embolic lesions in other organs. A post-mortem examination was performed the following morning.

Externally was seen a recent abdominal incision which appeared to be a healthy abdominal operation incision. The thyroid contained three adenomata, and was moderately enlarged. The tracheal and bronchial glands were small and pigmented. The lungs were healthy. The heart was obviously dilated. There was an increase in subpericardial fat. The right auricle was much dilated and the tricuspid valve admitted three fingers easily. The cusps showed chronic thickening. The coronary arteries were normal. The mitral opening admitted only one finger, and the cusps showed evidence of old sclerotic endocarditis with a superimposed recent acute endocarditis. Multiple small vegetations, with a small blood clot still adherent, were seen. Both cusps were affected. The aortic valve was competent, and the cusps showed very slight patchy thickening; the right posterior cusp showed a tiny vegetation. The abdominal aorta, which had been exposed and incised at operation, was found to be closed efficiently; there was no leak anywhere. On opening the aorta and its iliac prolongations there was found to be a very small adherent clot, and below in the iliac, especially the right external iliac, there was an adherent clot. The internal iliac was clear on this side. The veins appeared to be clear—this includes the popliteal femoral, and iliac. The right popliteal artery contained a clot, probably post-mortem. The aorta was notably small.

Brain.—Pia-arachnoid: there was a diffuse haemorrhage over the right occipital pole and the left frontal lobe. On section this was seen to be due to obvious recent infarction. Attached to the dura and tucked under the anterior pole of the right temporal lobe was a circumscribed mass which resembled endothelioma, although it might have been of circulatory origin—? infarction.

The spleen contained a recent large infarction in its upper pole. The upper pole of the left kidney contained a large infarction and evidence of an older one. The liver and other organs were healthy.

Comments.

The diagnosis was comparatively easy, owing to the lack of peripheral pulses in the legs.

This case also shows how it is possible safely to open the abdominal aorta and restore its integrity; and if the patient had lived long enough opportunity might have offered to study whether the wound of the artery would have led to any subsequent aneurysm or blocking of the vessel by later clotting.

The cause of death, in the light of the post-mortem findings, was evidently a sudden embolism which travelled towards the brain. There was no convulsion, but the patient died quite suddenly after appearing to rally from the operation. The loss of sensation very closely corresponded anatomically in its upper limit to the first lumbar nerve root on the surface; there was actual tenderness on pressure over the bifurcation of the abdominal aorta, and the striking feature of the case was the intense pain complained of, chiefly below and to the left of the umbilicus and in the left iliac region.

GLUCOSE: WHEN AND HOW TO USE IT.*

BY

F. P. DE CAUX, M.R.C.S., L.R.C.P.,

SENIOR HONORARY ANAESTHETIST, WOOLWICH WAR MEMORIAL HOSPITAL; ANAESTHETIST TO THE ROYAL DENTAL HOSPITAL.

WHEN I was a child I read a book entitled *Madam How and Lady Why*. Its author, in ennobling "Why" and making "How" a commoner, symbolized a profound truth; it is one thing to know the workings of natural phenomena, but quite another to discover the reason which underlies those workings. My old professor of chemistry used to say: "Don't bother too much about *why* things happen. If you know how they happen, can make them happen, and can control them while they are happening, it does not much matter what theory you use to explain your results."

My subject to-day is the use of glucose—chiefly as an antidote to the shock of operation and anaesthesia—and the mechanism of its working according to McDonagh's theory of electrical and other changes in the body protein, which he expounds in his book *The Nature of Disease*.

McDonagh's theory seems to me not only to explain much that was obscure in pathology, but also to show many directions in which physicians, surgeons, and anaesthetists can advance in their use of the means they already possess. Its exact truth does not matter so long as it helps us to get better results, and this it undoubtedly does. Its substance is as follows:

If the blood serum of a healthy person be examined under dark ground illumination it shows a large number of little globular refractile particles in colloidal suspension, exhibiting Brownian movement. These are known as protein particles; they exist throughout all the tissues of the body, but those of the blood are the most convenient for examination. Each protein particle can be compared to a solar system; its sun is the protein nucleus, and its planets, in the order of their distance from the nucleus, are fats, amino-acids, urea and uric acid, sugar, inorganic salts, and electrons. The whole system is kept together by water, as is the solar system by gravity. It is always being attacked by hostile substances, whether chemical products or micro-organisms, which tend to break it up. The most distant "planets," since they are the least closely attached, are the first to be split off. An invader, therefore, will strip off the electrons first; their electrical energy is dissipated in the form of heat and the body temperature rises. This appears clinically as fever. Then the salts are broken off; those which the plasma cannot hold are excreted in the urine. As the attack develops, the sugar, urea and uric acid, amino-acids, and, lastly, the fats, are reft from the protein nucleus and dissolved in the plasma, leaving the nucleus bare. In the end this itself fades away into true solution. Now as these planets are stripped away one by one, the water in which they swim is set free; the process is therefore called "dehydration." Some of the particles, however, undergo dispersion—that is to say, they subdivide to a certain point and there stop; there is a numerical increase and, in places where their volume exceeds that of the liquid present, the liquid and solid colloidal phases of the blood may be reversed. Instead of being a suspension of solid particles in a watery medium, it becomes a suspension of liquid globules in a solid medium; in other words, it "sets" like a jelly. This is called "gelation," and when it happens the patient suffers from intravascular clotting and thrombosis, which cause the clinical signs of cerebral sinusitis, hemiplegia, pulmonary embolism, and thrombosis, hyperemesis gravidarum, phlegmasia alba dolens, and a host of other conditions. Though gelation may occur primarily, it occurs more often secondarily, as a cyclical change of hydration. This explains why venous thrombosis is met with more frequently after operations and in the puerperium.

Now when the protein particles are being subjected to dehydration they do not follow one another like sheep. Only some of them are dehydrated—that is, split up into their constituent planets and driven into true solution, or dispersed; others resist the process, and they have only two means by which they can do this: one is to increase in size, the other is to agglutinate, or cling together. Since in both cases they take up water, they are said to become "hydrated," the opposite of dehydrated. When protein particles hydrate, their planets are at once drawn into a more intimate connexion with the nucleus and resist the more stoutly any attempt to split them off. Protein particles which have been hydrated tend to draw in upon themselves and work out their own salvation. Hydration is for the most part a defence mechanism.

* Read in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Manchester, 1929.

evoked by a slow, insidious chronic invader like cancer, chronic tobacco poisoning, syphilis, tuberculosis, or alcohol, and chronically hydrated protein particles are very difficult to reduce to normal.

Hydration may, however, also be produced suddenly, as by a drug with a large nucleus like insulin, which produces a considerable lowering of surface tension. When this happens, the swollen or agglutinated particles may be precipitated from the blood stream in masses large enough to block the capillaries. This change produces the condition known as shock, which may be cerebral, pulmonary, or splanchnic, according to the viscus in which precipitation chiefly takes place.

ANAESTHESIA AND THE PROTEIN PARTICLES.

The behaviour of the protein particles gives a valuable guide to the anaesthetist, first in preparing the patient and secondly in averting the ill effects of the shock which is inseparable from all anaesthesia. One of the most interesting facts which appear from a study of the protein particles is that anaesthesia and pregnancy affect them in very similar ways. The essential features of any anaesthetic are that it shall produce simultaneously a sudden dehydration of some of the particles and a sudden hydration and precipitation of the rest, in exactly the proportion required to cause unconsciousness. Pregnancy produces the same effect, with the difference that anaesthesia may do in seconds what pregnancy does in months. If the proportion is wrong, the same symptoms occur both in anaesthesia and in pregnancy. Excessive dehydration due to an anaesthetic causes vomiting; that due to pregnancy causes hyperemesis gravidarum. In anaesthesia and pregnancy alike the processes of dehydration and dispersion may continue to the stage of gelation and cause some form of venous thrombosis, such as pulmonary embolism. Excessive sudden hydration, on the other hand, produces the familiar condition known as shock.

The Treatment of Shock.

Shock is caused by sudden hydration of the protein particles and their consequent precipitation in the capillaries and pericapillary lymphatic vessels, which they obstruct. If they block those of the brain they produce fits, convulsions, coma, and sometimes death; if they block those of the lungs, they cause pulmonary collapse; if they block those of the abdominal viscera, the result is vomiting and diarrhoea. The lowering of the body temperature in shock is due to the adsorption of heat by the hydrating protein particles. In the worst forms of shock the blood collects in the big veins, in less severe forms in the important viscera. In mild or prolonged shock congestion is selective and confined to one or a few of the important viscera. The congestion due to anaesthetic shock selects first the brain, then the lungs, and finally the liver.

The value of glucose before, during, and after operation lies in its power of dehydrating rapidly those protein particles which have been hydrated by the shock of the anaesthetic and the surgical assault. The process can be watched under the ultra-microscope. When glucose is run into a field containing a number of slow-moving hydrated or waterlogged particles, some of which are agglutinated, the effect is almost miraculous: the agglutination breaks up, and the bulky spheres are shattered in a few seconds into multitudes of tiny globules. The same change takes place in the body, and the clinical effect is to pull a badly shocked patient together in a few minutes. The temperature rises, the colour returns, sweating ceases, and the patient settles down into normal respiration. Transfusion of normal blood produces the same effect, and for the same reason: it dehydrates the particles which the operation and the anaesthetic have hydrated in excessive numbers.

It is obvious that in treating acute shock the first consideration is to give enough glucose at once, and for this reason steps have to be taken to guard against an overdose. If exactly the right amount were given it would all be absorbed by the time the hydrated particles returned to normal, but in practice it is impossible to gauge the correct dose. Glucose is therefore given intravenously in large doses; the particles are dehydrated or dispersed, and the symptoms of shock pass off. But the protein particles, though they are brought back to normal, will not remain so, because they are unstable. They have lost their electrons, their furthest planets, or else they would never have become hydrated. They therefore proceed past the normal stage into dehydration and dispersion; they are broken up into their component planets and greatly increased in number, and, if the process is not checked, gelation and thrombosis occur. There are two ways of checking the dehydrating action of glucose so as to avoid thrombosis. One is to give fifteen to twenty units of insulin, a powerful hydrator, about two hours afterwards, when the glucose has exerted its maximum effect. This prevents too many particles being sent into true solution by the glucose. The other method is to give a "conductor," or a substance which will supply the particles with the electrons they need and stabilize them. Conductors are of no value when hydration or dehydration have progressed far, but are very valuable in the initial stages, when only electrons are lost, and also when particles are passing through the normal phase on their way from one abnormal phase to the other. One of the most effective conductors is S.U.P. 36, or, to give it its full name, the symmetrical urea of para-benzoyl-para-amino-benzoyl-1-amino-8-naphthol 3:6 sodium sulphonate. S.U.P. 36, like insulin, should be injected on the first sign of recovery. Oxygen acts like glucose when given subcutaneously, but it is not so potent. It is therefore usual to give intravenous glucose with subcutaneous oxygen in severe cases only, but in mild ones to neglect the glucose and merely give 500 to 1,000 c.cm. of subcutaneous oxygen. Oxygen acts so mildly that there is no fear of dehydrating the protein particles excessively; insulin is therefore unnecessary.

PREPARATION OF PATIENTS FOR ANAESTHESIA.

Chronic alcoholics, late-stage syphilities, and patients with malaria, trypanosomiasis, cancer, and other chronic ailments are notoriously difficult to anaesthetize. There are two reasons for this. The first is that their protein particles have been subjected to a long and increasing process of dehydration, and there are not enough normal particles left to undergo the chemico-physical changes necessary to bring about anaesthesia. The second reason is that many of the protein particles left in the colloid state have undergone secondary hydration, and the first effect of the anaesthetic—namely, dehydration—upon these enlarged particles is to cause them to undergo dispersion. The normal process of anaesthesia cannot take place until the hydrated particles are broken down and then subjected again to hydration by the anaesthetic. These patients therefore need preparation for some days beforehand with intravenous injections of colloidal iodine, and intramuscular injections of sulphur in the form of contramine, the carbon disulphide compound of di-ethyl amine.

Purging and starvation should be, and rightly have been, relegated to the limbo of barbaric things, as they exhaust the glycogen reserves of the liver, the patient's natural defence against shock, and produce the very condition which the anaesthetist is trying to avoid. It is always desirable, especially in the bad risk case, to examine the patient's protein particles several days beforehand. If hydration is present a course of intravenous colloidal iodine and of intramuscular contramine should be given; the night before the operation glucose should be injected intravenously, together with subcutaneous oxygen. The colloidal iodine and contramine act slowly, and in obstinate cases may require several weeks to produce the desired result. The glucose is given slowly, at the rate of about half a litre an hour. It is stored in the liver, and given out as required to correct excessive hydration due to operation or anaesthesia.

POST-ANAESTHETIC TREATMENT.

If most of the particles are dehydrated after operation (and this is not likely until the third day or later), the patient should be given insulin, but it is important not to give insulin if many particles are hydrated, for the sudden increase in hydration which it produces may cause fatal shock. The clinical signs of post-anaesthetic gelation are a rise in temperature and vomiting, cyanosis, or fits, according to whether thrombosis takes place in the splanchnic vessels, lungs, or brain. If the disturbance is in its initial stages and the temperature is high, S.U.P. 36 should be exhibited, but if two or three days have elapsed

since the operation and the patient is still vomiting, insulin should be given. When post-anaesthetic hydration is feared, intravenous glucose and subcutaneous oxygen should be administered rapidly, any excess of glucose being excreted by the kidneys. Pulmonary hydration is especially likely to occur after prolonged anaesthesia in a bad subject if the patient has recently received an injection of a substance with a large nucleus and high molecular weight, such as intravenous arsenobenzene or S.U.P. 36. Glucose and oxygen should therefore be given to all patients who are under treatment for syphilis.

A rough and ready test for determining whether the vomiting is due to splanchnic shock—caused by the precipitation of hydrated protein particles in the abdominal viscera—or to dehydration of protein particles, is to draw off some blood in a syringe. If the blood flows readily and is bright red the protein particles are probably hydrated, but if it flows with difficulty, clots rapidly, and is dark in colour the particles are probably dehydrated. It is most important to determine which condition is present, as the wrong treatment will only accentuate the disorder it is desired to remedy.

The Orthodox Attitude to Glucose.

Surgeons have recognized the value of glucose without, for the most part, understanding its action. The general tendency is to focus attention on ketosis, which is one of the by-products of shock, and to counteract it by giving glucose in the belief that it replaces the large quantities of sugar consumed in the state of shock or under anaesthesia. The empirical surgical attitude, which is correct within limits is well represented in Barrington-Ward's book *The Abdominal Surgery of Children*. The author rightly eschews purgatives and enemata, and provides the child on the day before the operation with a full diet and a bottle of barley sugar. A light meal and more barley sugar are given on the morning of the operation. When the operation is severe or the patient's resistance appears to be low, a 5 per cent. solution of glucose is given subcutaneously during the thirty-six hours before operation. Older children receive a 10 per cent. solution of glucose in water per rectum. In very anxious cases transfusion is performed and salines are injected during the operation. For the treatment of post-operative ketosis Barrington-Ward gives 10 per cent. glucose per rectum every four hours, or 5 per cent. glucose intravenously, preferably by Matas's drip method. His remarks on alkaline treatment are very interesting from McDonagh's point of view. Quoting the work of Brown and Graham, he says that sodium bicarbonate cannot be depended upon to reduce the acetone in the blood and urine, but is beneficial in producing a rapid return to normal of the low alkali reserve. Glucose, on the other hand, he remarks, causes a rapid diminution of the blood and urine acetone as well as a rise in the alkali reserve, and arrests the formation of ketone bodies. While advocating large doses of sodium bicarbonate as an adjuvant, he definitely gives it second place. The reason for the success of glucose is, of course, not that it substitutes missing sugar, but that it goes straight to the root of the trouble and dehydrates the protein particles. This is proved by the fact that other chemicals which cannot replace sugar, such as di-hydroxy-acetone and adrenaline, produce the same result.

The Technique of Glucose Administration.

Glucose solution, to exert its full effect, must be used within twenty-four hours of its preparation. I always use and recommend a 10 per cent. solution at a temperature of 100° F. Before an operation it must be given slowly, or it will rapidly be excreted by the kidneys. When it is administered slowly any excess is absorbed by the liver as glycogen and let loose into the blood stream in the form of glucose as required. If the patient's protein particles are already hydrated, the glucose can be given faster than when it is merely desired to increase the glycogen reserves.

The use of glucose at operations can be summarized as follows:

A. Always give glucose before a severe operation: (1) when the liver efficiency is suspected—for example, where there is a history of jaundice; (2) when the metabolic rate is high—for example, in Graves's disease; (3) when the patient is undernourished or emaciated.

B. Always give glucose after a severe operation when a blood transfusion is impossible.

C. Give glucose after any anaesthetic: (1) where loss of blood has been heavy and blood transfusion is not practicable; (2) where the patient shows signs of shock—cerebral, pulmonary, or splanchnic; (3) where glucose has not been given before the anaesthetic; (4) where a rough surgeon has operated, or where it has been necessary to use more than the usual amount of anaesthetic; (5) where there is a history of epilepsy.

TRAUMATIC RUPTURE OF THE STOMACH.

BY

F. E. BOLTON, M.R.C.S., L.R.C.P.,

LONDON.

In the *British Medical Journal* of July 27th Mr. F. Hector Scotson published two very interesting cases of rupture of the stomach alone, from external non-penetrating violence, which, owing to absence, I have only just seen. That this condition is very rare is evidenced by the literature on the subject from British sources which he has so ably collected.

It may be of interest to quote some extracts from foreign literature on the subject before recording a case under my care in 1927.

Rehn[1] in 1896 collected 13 cases, of which only 2 were uncomplicated. Only 2 recovered, including Rehn's own case.

A. Schwarz[2] in 1909 reported one fatal case in which both stomach and duodenum were completely torn through.

A. Piancastrelli[3] in 1922 stated that only 22 cases of traumatic subcutaneous rupture of the stomach could be found in literature. In his case, the twenty-third, which proved fatal, the abdominal wall under the skin was ruptured and the stomach almost divided in half.

G. Ipsen[4] quotes a case of his own in the same year, in which the rupture was in the pylorus, and the patient recovered.

H. Neuberger[5] quotes a fatal case of his own in which there was also injury to the pancreas. He is of opinion that the grave prognosis in these cases is due to concomitant injury to the ganglion coeliacum, which lies dorsally to the stomach.

From this it will be seen that only 9 cases were of rupture of the stomach as the only viscus, and that only 3 recovered.

My own case, like those of Mr. Scotson, showed no signs of external injury, and was not complicated by injury to any other viscus.

A seaman, aged 29, was admitted to the Royal Naval Hospital, Malta, on January 27th, 1927, with a history of having fallen from a ladder and been struck in the lower abdomen by a piece of iron projecting about 12 feet below. He had had a full meal about one and a half hours previously. The patient, a very small, spare, and well-developed man, was groaning and doubled up. There were signs of shock, and the pulse was 92. There was no sign of any injury to the abdominal wall. The abdomen generally was held rigid, but was not board-like, and the patient sat up to take off a tight garment. There was no dullness in the flanks. The liver dullness was present, and there was no hyperaesthesia to pin reflex. Pain was referred to the lower abdomen and radiated down to the testicles. Clear urine had been passed twenty minutes before examination. He was suffering from marked shock, and groaning, with intervals of quiet.

In the absence of any marked physical signs I decided, wrongly as it turned out, to wait for further signs; after five and a half hours the pulse rose to 120, there were distinct signs of tympanites, and the leucocyte count was 15,300. He was therefore given a general anaesthetic, and the abdomen was opened by a right central paramedian incision. The peritoneal cavity was found to be full of turbid fluid. On swabbing this out it was found to be coming from the right upper quadrant. The incision was therefore extended upwards. A hole with everted mucous membrane, and easily admitting the forefinger, was found on the anterior surface and near the greater curvature in the pyloric end of the stomach. Its appearance was almost identical with the picture of this condition in Walton's *Surgical Dyspepsias*. There were no signs of any ulcer present. The gall-bladder was covered with a lymphatic exudate. The liver edge was bruised but not torn. There were no signs of injury to any other viscus. The burst was sewn with Lembert over primary deep sutures, peritoneal toilet performed, and a drainage tube was placed in the under surface of the liver.

The patient was almost pulseless at the end, and nearly died of shock, although the operation did not take long owing to the patient's favourable build. Severe shock lasted for twenty-four hours, but was overcome by intravenous glucose saline. He

eventually made a good recovery and returned to duty. He was well and fit a year afterwards, when I last heard of him, and suffered no inconvenience.

In this case the shock, as compared with a case of perforated ulcer, was out of all proportion to the injury and the subsequent operative "manhandling," and suggests Neuberger's theory that in these cases there is usually some damage to the coeliac ganglion.

AUTO-BLOOD-TRANSFUSION IN TWO CASES OF RUPTURED TUBAL PREGNANCY.

BY

H. B. BUTLER, F.R.C.S.ED.,

SURGEON TO THE GYNAECOLOGICAL DEPARTMENT, ROYAL SURREY COUNTY HOSPITAL.

AUTO-TRANSFUSION, first used in Germany by J. Thies in 1914, appears to have found more favour in that country than in England or America. Reports received are, however, eminently satisfactory, and it is difficult to understand why the method is not more frequently adopted in cases of emergency, when much recoverable blood has been lost. Two cases illustrating its value are here recorded.

CASE I.

A woman, aged 36, who had been married eleven months, was admitted to the Royal Surrey County Hospital at 11 a.m. on June 14th, in a collapsed condition. No pulse could be felt at either wrist, and there was considerable dyspnoea. She was conscious. She had had amenorrhoea for two months, and had remained well until the evening before admission, when, at 8 o'clock, she was attacked with violent abdominal pain, diarrhoea, and vomiting. Thinking that the attack was due to some error of diet, her husband gave her castor oil, brandy, and gin. She spent the night in great agony, and fainted in the morning; arrangements were at once made to remove her to hospital. Her menstrual history had been normal except for dysmenorrhoea; she was curetted at the age of 23 with some improvement, and there had been no dysmenorrhoea after marriage.

Operation.—The abdomen was opened and found to be full of blood, which was mostly fluid, but there were many large clots. Three pints of it were ladled out of the abdomen into a large jug; the larger clots were rejected, but many clots went into the jug. This blood, strained through several layers of gauze, was citrated and 1½ pints were transfused into a vein in the right arm by my colleague Mr. Steele. The left tube was found to be ruptured at the ampulla and was removed. The ovum was not seen. At the end of the operation the patient had a small but countable pulse, and by evening her condition had ceased to cause anxiety. Convalescence was smooth and uneventful.

No suitable donor was available at the moment, and I feel certain that the reinfusion is responsible for saving the patient's life.

CASE II.

A married woman, aged 38, with nine children, the youngest aged 1 year and 4 months. The last menstrual period ceased on October 5th, 1929. At 7 p.m. on October 29th she was taken with sudden severe abdominal pain, which continued throughout the night. She was admitted to hospital in a collapsed condition at 1.30 p.m. on October 30th, completely blanched; the pulse was just palpable, but not countable, and could not be felt at all during her preparation for operation, though it was just palpable at the wrist immediately before operation.

Operation at 2.30 p.m. under gas-oxygen anaesthesia. Three measured pints of blood were rapidly ladled out of the abdomen and put into a jug, being filtered through several layers of gauze. This was again filtered into another jug containing the appropriate quantity of the solution of sodium citrate, and from thence infused into a vein in the right arm by Mr. Steele, the infusion being finished at the same time as the operation. The left tube was ruptured in its middle portion and was removed; the ovum was not seen.

The patient went back to bed in good condition. There was very little coagulation of blood in the abdomen, and she must have recovered a very large proportion of the blood she had lost. There was no shock or reaction, and at 6 o'clock the same evening she was sitting up in bed with a good colour, talking to her neighbours, a little excited by her adventure, but otherwise none the worse. There has been no hitch in her recovery to date.

Presumably the dislike of reintroducing into the circulation blood which has been lying in the abdomen is due to the fear of sepsis or of the blood having acquired some toxic character secondary to congulation. As a student I was taught that the raised temperature, which so frequently accompanies the process of absorbing blood which has been effused into the tissues, was due to the absorption of *fibrin; but from the recent experiments* of Horace Greeley,[1] it seems likely that the poisonous property is present, or also present, in the defibrinated blood, and is dependent on the disintegration of platelets. When there is no reason to suspect contamination, the danger of sepsis does not appear to be a large one, as no cases of septicaemia following autotransfusion have been reported. Burch[2] recommends that blood, even when known to be contaminated, should not be thrown away, but should be given as a rectal drip.

The fear that reinfused blood may have some toxic action is not confirmed by a study of the reported cases. Topler[3] reports twenty-four cases of smooth recovery after reinfusion, in ruptured extrauterine gestation; similar success accompanied Burch's four personal cases. In the 164 cases reported in European literature (collected by Burch) there were only fourteen deaths, and of these only one (haemoglobinuria) could possibly be attributed to the toxic character of the blood reinfused. In only six cases was there a post-operative reaction. It may be that this immunity is due to the tendency of blood which has been effused into the peritoneum or pleura to remain fluid for a considerable time, thus enabling whole unaltered blood to be used for transfusion, any clots being strained off in the gauze without breaking them up. Two of Burch's cases were ruptured tubal pregnancies; another was a case of splenectomy, in which much blood had been lost, and the fourth a *nephrectomy*. Burch says (1923) that "two cases are reported in English literature, one by Dr. Ogilvie of Guy's Hospital, and one by Sampson of the General Hospital, Birmingham." Mention may also be made of the case reported by Devine and Kinsella (*British Medical Journal*, 1928, vol. ii, p. 568), in which auto-transfusion was successfully employed for traumatic intra-abdominal haemorrhage in a boy aged 12.

In a recent article by Lilian K. P. Farrar[4] the early history of auto-blood-transfusion is traced from the first suggestion by William Highmore in 1874[5] to two articles by Duncan[6] in 1885 and 1886. In Duncan's second article he states: "I make it a practice in all larger amputations, because there is no risk and every ounce of blood is serviceable; . . . to my own mind the principle of reinfusing the patient is now definitely established." Nevertheless, the practice seems to have lapsed until it was reintroduced by Thies in 1914. Dr. Farrar kept sealed ampoules of sodium citrate solution in the operating room, ready for auto-blood-transfusion in cases of ruptured tubal pregnancy, but the frequent changes of personnel made it impossible to secure all the help required for the transfusion when the operation itself needed her entire attention. She concluded that the necessary team work could only be obtained by frequent practice of the technique in simpler cases, and arranged to try the measure in clean hysterectomies for myoma uteri. She was surprised to find the transfusion so valuable in these simpler cases.

Except in cases where large quantities of blood have accumulated in the abdomen, Dr. Farrar collects the blood by a suction apparatus. She points out that sponges should never be used, as the squeezing out injures the red cells, and, for the same reason, care is taken not to shake or stir the blood.

Dr. Farrar reports twelve cases, the last being especially dramatic. She says that the technique could not have been carried out in such a grave emergency if the staff had not been trained to team work in the simpler cases.

SARCOMA OF SMALL INTESTINE.

Report of Three Cases.

BY

DOUGLAS ROBB, M.D., F.R.C.S.Eng.,

Assistant Surgeon, Auckland Hospital, New Zealand.

The article by Messrs. Moir and Walker on sarcoma of the small intestine, in the *British Medical Journal* of December 29th, 1928, prompts me to record three further cases.

Case I.

Mrs. J. P., aged 59, was admitted to the Auckland Hospital complaining of passing much dark blood per rectum for twenty-four hours. She had not vomited. She had suffered from indigestion for years. Her condition was very low from loss of blood. A transfusion of blood and a subcutaneous injection of

Sarcoma of duodenum (Case I). A, Pylorus. B, Bristle emerging from bile duct. C, Centre of one half of tumour. D, Other half of tumour, area of haemorrhage. E, Termination of duodenum.

normal saline were given; but the patient gradually sank, and died within twelve hours of admission.

Necropsy revealed the scar of a healed ulcer in the first part of the duodenum. On the lateral aspect of the lower end of the second part of the duodenum a spherical solid tumour the size of a walnut was found. It appeared to be growing from the muscular coat of the duodenum, being well encapsuled where it lay in contact with the head of the pancreas. It projected slightly into the lumen of the duodenum, being covered loosely, in this area, by mucosa, except at the most elevated portion. At this point the termination of a vessel about 1 mm. in diameter was seen lying in the tumour, its lumen plugged with recent clot. This vessel had doubtless been the source of the haemorrhage. On section the tumour was whitish and firm, except in two or three areas where haemorrhage had occurred. Microscopically the tumour was a spindle-celled sarcoma, remarkably uniform throughout, with areas of haemorrhage. No metastases were found.

Case II.

Mrs. E. K., aged 23, was admitted to the Auckland Hospital in a very exhausted and toxic state. Two gallons of fluid were withdrawn from the abdomen. The patient sank, and died the next day. Three years before her death she had had a lump removed from the left groin. It was a well-encapsuled egg-shaped growth in the region of the femoral glands, and was black on section. Microscopically it was a melanoma, intensely pigmented, with no trace of lymphoid tissue. The wound was slow in healing. A melanotic mole one-eighth of an inch in diameter was noticed on the calf of the leg. Sixteen months before her death she had been again admitted, this time for nagging pain in the right side of the epigastrium of three months' duration. A mass could be felt, and x-ray photographs showed constant irregularity in the upper half of the descending portion of the duodenum. Laparotomy revealed a "large pyloric and duodenal mass which was melanotic." A small portion was excised for microscopical examination and the abdomen closed.

At necropsy a large melanoma occupying the whole circumference of the wall of the second and third parts of the duodenum was found. The lumen was greatly enlarged and was lined by the necrotic surface of the tumour. The common bile duct was obstructed. At no point did the growth penetrate the peritoneal coat of the duodenum, and at its upper and lower limits its edges were heaped up and sharply defined, as in an epithelioma. No other metastases were found. Microscopically the growth was a heavily pigmented melanoma, submucous in origin, though the mucosa was lost everywhere except at the edges.

Case III.

Mr. D. M., aged 60, sought advice on account of increasing pallor, which was causing anxiety to his family. He said also that he suffered from vague nausea and anorexia, slight constipation, and a loss of business acumen. Ten years previously he had had a mole removed from behind the right ear, and nine years previously a large mass of glands from the right side of the neck. Neither of these tissues was examined microscopically, but the former was believed to be a melanoma, and the latter malignant, and secondary to the mole. A bad prognosis had been given after the second operation, which was undertaken at the wish of the patient.

Examination revealed a marked pallor suggesting pernicious anaemia. The blood picture showed the changes of an ordinary secondary anaemia, without abnormal cells. In the abdomen a mass the size of a large orange could be felt to the left of the umbilicus. It was apparently free from the spleen, kidney, and stomach, being mobile but not influenced in position by respiratory movements. It was slightly tender.

Operation was undertaken, and a large bulbous growth in the jejunum, 16 inches from the duodeno-jejunal flexure, was resected and an end-to-end anastomosis performed. No metastases were discovered in the mesenteric glands or liver. Normal convalescence was reported until the fifth day, when sudden death occurred. This was attributed to a cardiac condition. A post-mortem examination was not made.

Examination of the specimen showed a segment of jejunum about three inches long to be greatly enlarged by a heavily pigmented growth occupying the whole circumference of the wall of the bowel. The thickness of the growth varied from half an inch to one and a half inches; its edges were sharply defined and heaped up; the lumen was enlarged, and lined by the surface of the growth, which at no point penetrated the peritoneal coat. Microscopically the tumour was a melanoma.

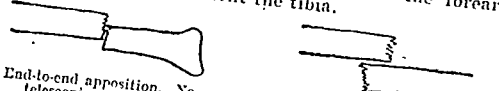
I am indebted to Mr. Eisdell Moore, Mr. Kenneth Mackenzie, and Mr. Frank Macky, under whose care these patients were admitted, for permission to publish these notes, and to Dr. W. Gilmour, director of the Auckland Hospital laboratory, for advice on the pathological side.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TELESCOPIC MOVEMENT IN FRACTURES.

The above is a sign I have not previously seen described, but have found very useful in deciding if one has secured end-to-end apposition in the reduction of fractures of long bones. It is comparable to the "telescopic motion" in congenital dislocation of the hip-joint, but is more easily and certainly elicited than the sign in hip-joint dislocation. It is particularly useful in transverse, or approximately transverse, fractures of the shafts of those long bones which are well covered by muscles, such as the forearm, the thigh, and to a less extent the tibia.



End-to-end apposition. No telescopic movement.

Failure of reduction. Telescopic movement present.

For example, take the common fracture of both bones of the forearm with displacement of the fragments, causing loss of end-to-end apposition. With the patient under ether anaesthesia, helped if available by a radiogram, the fractured ends of the radius are palpated, and then, by increasing the deformity, a purposive movement is made to secure end-to-end apposition of the radius. The limb is then straightened, and a gentle attempt to telescope the forearm is made. If end-to-end apposition has been secured no telescopic movement can be obtained. It may be necessary to manipulate several times before telescopic movement is lost. The ulna with its palpable subcutaneous

surface is more easily dealt with, and the forearm plastered in supination. The routine radiogram after reduction is then taken.

The same principles apply to transverse fractures of the femur, but here, owing to the bulk of the limb, reduction is more difficult, and it is important to manipulate the fracture in the first few hours before adaptive shortening of the muscles has occurred. After reduction the ordinary methods of extension are applied. The oblique fracture of the shaft is usually easily corrected by the ordinary methods of extension.

D. C. Corry, M.D., F.R.C.S.,
Assistant Surgeon, Radcliffe Infirmary, Oxford.

DIABETES MELLITUS AND HEREDITY.

In his interesting article in the *Journal* of October 27th, 1928 (p. 738), Dr. P. J. Cammidge called attention to the great importance of the heredity factor in diabetes mellitus. The following case now under my care bears out his conclusions in a striking way.

A married woman, aged 31, complained of great lassitude and thirst; she dated her illness from the birth of a stillborn child some months previously. On examination the urine was found to contain large quantities of sugar, and both the patient and the mother, who was with her at the time, expected a diagnosis of diabetes, on account of the family history. Similar though milder symptoms had manifested themselves some three years previously, after she had obtained employment in a sweet shop. She then married and, two years later, gave birth to a stillborn child. Since then the disease had become much worse, but she has steadily improved under treatment.

The family history is interesting. Two sisters and one brother have died from diabetes mellitus, their ages being 30, 17, and 13 at the time of death. Another sister has had glycosuria—her present condition is unknown. The mother and father appear to be healthy.

In a rapidly fatal case of diabetes mellitus in a child aged 15 months under my care about the same time, there did not seem to be any hereditary factor—so far as could be ascertained. At the post-mortem examination acute miliary tuberculosis was also found, and the father is suffering from pulmonary tuberculosis at the present time.

Bristol. Joseph A. Parkes, M.B., B.S.

RUPTURED DERMOID CYST.

The interest in the unusual abdominal catastrophe recorded below lies not only in the rarity of the condition as seen at operation, but also in the difficulty of making an accurate diagnosis before operation.

A girl, aged 14, who had never been ill in her life, and had never before complained to anyone of pain or discomfort, was playing in the garden with a baby sister when, in the act of lifting the baby from the ground, she felt an acute pain in the upper part of the abdomen; so acute was the pain that she fell down and was unable to rise. Her mother, attracted by her screams, obtained help and carried her into the house. Dr. Price of Castle Cary recognized that an acute abdominal catastrophe had occurred, and sent her by ambulance into the Wincanton and East Somerset Hospital.

When I saw her, about half an hour after her arrival in hospital, she was lying on her back with her knees drawn up, obviously in very acute pain and suffering from severe shock. Her face had an anxious expression, and she was very pale. The temperature was 101°, and the pulse rate 125. The tongue was clean and moist. The abdomen was hard and board-like over its whole extent and very tender. She pointed to the epigastrium as the maximum point of tenderness and pain. There was an area of absolute dullness extending from about one inch below the liver on the right side down to the pelvis. The whole of the left side of the abdomen was tympanitic. The girl was not menstruating and had never done so. Examination per rectum revealed nothing except general tenderness.

I decided on an immediate operation, making a right para-median incision, with its centre opposite the umbilicus. On incising the peritoneum a quantity of creamy fluid escaped; since there were several small bunches of hair in this fluid it became obvious that we were dealing with a ruptured dermoid cyst. On enlarging the opening I found a huge multilocular dermoid tumour of the right ovary filling up the whole of the right side of the abdomen, and extending as high as the epigastrium; it almost touched the right lobe of the liver. The largest cyst of this tumour had ruptured at its highest point close to the pyloric end of the stomach; the hole easily admitted three fingers. The tumour was lifted out of the abdomen and removed.

The only difficulty encountered at the operation was that of cleaning the abdominal cavity, which was flooded with the creamy fluid containing innumerable semi-solid masses resembling cream cheese and scattered bunches of hair. A stream of saline solution was directed to all parts of the peritoneal cavity, and these foreign substances were removed as they floated to the surface. The great omentum was very hard to clean since the cheesy substance and hair were so intimately adherent to it that it had to be gently wiped with swabs wrung out of saline solution. The abdomen was closed with drainage, and the patient's recovery was uninterrupted.

The tumour was rather larger than an elongated adult head. It was composed of solid parts of almost the consistency of cartilage, and several daughter cysts; one of these was much larger than the rest, and it was this one which had ruptured.

Thomas E. Coulson, M.D., F.R.C.S.Ed.,
Honorary Surgeon, Wincanton and East Somerset Hospital.

Reports of Societies.

ACUTE MASTOIDITIS WITH EXTENSIVE THROMBOSIS.

The Aberdeen Medico-Chirurgical Society met at the Aberdeen Royal Hospital for Sick Children on November 7th, with the president (Professor Low) in the chair; a demonstration of clinical cases was given by members of the staff.

Dr. Souper described a case of acute mastoiditis with lateral sinus and internal jugular thrombosis.

A boy, aged 10, was admitted to hospital with a history of acute pain in the left ear for one week and discharge from that ear for one day; his temperature on admission was 103.6°. There were no signs of mastoiditis, and he was kept under observation as a case of acute suppurative otitis media threatening complications. His condition did not improve for forty-eight hours, when a blood culture showed the presence of haemolytic streptococci, and an operation was performed under gas and oxygen anaesthesia. The mastoid cells were found widely infected and the lateral sinus thrombosed. The jugular vein was exposed in the neck, and on incision was found to be also thrombosed as far down as it could be dissected. The sinus was cleared of clot; the jugular vein was tied as high and as low as possible and excised, the facial vein being also tied off. At the end of the operation 300,000 units of scarlet fever antistreptococcal serum was injected intravenously. The following day the condition of the patient was extremely grave; there was a loud musical bruit at the apex of the heart, and acute nephritis, with albumin, blood, and casts in the urine. Six similar doses of serum were administered within ten days of the operation, and by the end of a fortnight the condition of the patient was satisfactory. The blood culture was sterile, the cardiac bruit had disappeared, and the urine was normal.

Dr. Souper was of the opinion that recovery was mainly due to the use of this serum. Since April, 1927, he had employed it in his cases of septicaemia, ten or twelve in all, mostly with haemolytic streptococci of aural origin. Every patient had recovered with one exception, in whom a late thrombosis in the jugular bulb occurred. In similar cases he had previously used ordinary antistreptococcal serum, intravenous mercurochrome, and other remedies, but without success. He suggested that where septicaemia was due originally to infection from the throat or nose the scarlet fever serum should be used. He was indebted for the suggestion to make use of this serum in the first instance to Dr. John Smith of the Aberdeen City Hospital.

Infections of the Spine.

Mr. Mitchell brought before the society a boy, aged 7, who had had pain in the back and loss of weight for a year. There was scoliosis of the dorsal region of the spine with curvature to the right, and slight kyphosis; the last dorsal and first three lumbar vertebrae were prominent, and there was pain in the lumbar region on jarring the spine. The boy walked unwillingly with a crouching gait, supporting himself by holding his thighs. There were no signs of pressure on the spinal cord or nerve roots, and the Wassermann reaction was negative. An *x*-ray examination revealed lesions involving three pairs of vertebrae, ninth and tenth thoracic, twelfth thoracic and first lumbar, and third and fourth lumbar. Mr. Mitchell did not think the lesions were tuberculous, since they were multiple, but suggested the possibility of a multiple septic infection.

Dr. John Craig showed a case of extramedullary spinal tumour in a girl, aged 8. There had been root pains for eighteen months, with some loss of power and stiff gait

for about three months. Motor and reflex signs localized the lower level of the tumour at the fourth lumbar segment, and sensory and reflex signs placed the upper level at the tenth dorsal segment. The cerebro-spinal fluid showed a modified Froin syndrome—xanthochromia, increase in the globulin, and only 4 cells per c.mm.

Mr. ANDREW FOWLER demonstrated a case of tuberculous disease of the spine.

FAMILIAL ATAXIA.

A MEETING of the Manchester Medical Society was held in the society's reading room at Manchester University on November 6th, when Dr. FERGUS R. FERGUSON read a paper on the familial ataxias.

Dr. Ferguson said that the term "familial ataxia" was originally employed to denote a number of cases of ataxia with an hereditary or familial incidence, but it had come to be used to include a variety of different diseases, many of which showed little or no ataxia. The tendency had been to regard these diseases as more or less distinct and separate entities, although for the sake of convenience they were generally included in a neurological textbook under the heading of "heredo-familial ataxias." The group of diseases referred to included Friedreich's ataxia; Marie's ataxia; Sanger Brown's ataxia; Neff's ataxia; families described by Klippel-Durante, Cestan and Guillain, Ballet and Rose, Batten, and Miura; so-called familial disseminated sclerosis; and familial spastic paralysis. In showing the chaotic state of this group Dr. Ferguson called attention to the fact that cases of Sanger Brown and Neff's ataxia were confined to the original family. Gordon Holmes had clearly shown that there were large numbers of cases masquerading under the title "Marie's ataxia" which were quite unlike Marie's original "hereditary cerebellar ataxia"; that in fact "Marie's ataxia" was now largely a "scrap-heap." The speaker emphasized the importance of bearing clearly in mind the various factors which might be involved in these affections—namely, psychological influences, the cranial nerves, and pyramidal, extrapyramidal, sensory, and cerebellar tracts; he pointed out how the clinical picture varied according to the degree and extent to which these systems were affected. The probable close similarity, or even unity, of these various diseases was suggested by the occurrence of Friedreich's ataxia and Marie's ataxia in the same family, as reported by Bayer and G. Perrier and Chassin; the transition types between Friedreich's and Marie's ataxia, as recorded by Perrero, Lenoble, and Margulies; and the evidence brought forward in respect of a family investigated by Dr. Macdonald Critchley of London and himself, and reported in *Brain* (1929). In this family thirteen members were affected, and most of the cases showed the following characteristics: (1) age of onset 35–45; (2) euphoria and emotional instability; (3) ocular paralyses, nystagmus, and optic atrophy; (4) evidence of pyramidal disease; (5) wide-spread sensory disturbances; and (6) certain extrapyramidal manifestations. Now although this was the composite picture, yet some of the cases resembled superficially and had been diagnosed as Parkinson's disease, and others as disseminated sclerosis. It was obvious that although most of the systems were involved in each case, the clinical picture depended upon the degree to which these systems were affected. Dr. Ferguson suggested that, although post-mortem evidence was lacking, probably all the cases had a common pathological basis—an hereditary abiotrophy of the neurones. He thought that there was extremely good clinical evidence that in all probability there was no essential difference between all these types which had been regarded by many observers as distinct and separate entities, and that the different clinical pictures in the various "familial ataxias" only resulted from the extent and degree to which the various systems—psychological, cranial nerve, cerebellar, sensory, pyramidal, and extra-pyramidal—were affected.

Hydatid Disease of the Lung.

Professor E. D. TELFORD read a communication on the subject of hydatid disease of the lung, and described two cases, with radiograms. The first patient was a boy, aged 14, from whom a large cyst of the lung had been easily and successfully removed by thoracotomy. In the second case a woman, aged 40, had made a complete recovery after the spontaneous expectoration of two very large hydatid cysts of the lung. The speaker emphasized the frequency of multiple cysts in the same patient, and produced evidence to show that the hydatid cyst was of much slower growth than was commonly supposed. The difficulties of diagnosis were discussed, with special reference to eosinophilia, anaphylactic phenomena, and the complement fixation and Casoni tests. The treatment of lung hydatids was considered, and the view was expressed that small hydatids deeply placed in the lung might respond better to expectant treatment; hydatids near the pleural surface should be submitted to operation, owing to the risk of rupture into the pleural cavity.

BISMUTH TREATMENT OF LUPUS ERYTHEMATOSUS.

AT a meeting of the Liverpool Medical Institution, on November 14th, Dr. R. M. B. MACKENNA read a note on the treatment of lupus erythematosus by intramuscular injection of bismuth.

Dr. MacKenna commenced with a rapid summary of the etiological and pathogenetic factors, and stated that it was generally held that the disease was the manifestation of a chronic toxaemia. Three forms of the disease were commonly found to-day: the first exhibited erythematous scaly lesions; in the second there were indurated lesions, with little scaling or erythema, but with horny plugs in the orifices of the sebaceous and sweat glands; while the third type showed marked erythema but few scales. Lantern slides of the condition with a photomicrograph of a section of the diseased skin were shown. A brief reference was made to the original paper on this subject by Nicolas, Lacassagne, and Rousart, and Dr. MacKenna then contrasted and compared the various forms of bismuth used and the methods of administration. Metallic bismuth and its oxychloride were, in his opinion, of equal therapeutic value in the treatment of lupus erythematosus. Injections of sodium bismuth thioglycollate had not yielded better results than other preparations; bismuth given by the mouth and in an ointment basis were not, he considered, of much value. It was impossible to estimate how much bismuth any given case would require, or for how long treatment would have to be continued. Of twenty-four cases treated by injections of bismuth since March, 1929, approximately 25 per cent. were discharged as cured, 25 per cent. would shortly be discharged as cured, and remaining 50 per cent. were making variable progress. In conclusion, the lecturer stated that he had no proof that the cases discharged as cured were really cured; it was possible that bismuth injections might only cause a temporary intermission in the course of the disease. He could give no information about the mode of action of bismuth in lupus erythematosus.

Skin Eruptions Caused by Fungi.

Dr. ELIZABETH HUNT gave a brief preliminary report on some forms of skin eruption which were said to have become more prevalent and to be due to fungi. The organisms isolated on culture were: (1) Yeast-like fungi, including red, white, and pink cryptococci, monilia, cudomyces, torula; and (2) trichophytons, including epidermophytons. It was impossible to distinguish clinically the type of lesion due to the different organisms. Cases occurred, as a rule, as isolated instances in a household, and indirect infection seemed most likely to be responsible. An "individual susceptibility" of the skin might be inferred, but the hypothesis required investigation. Temporary reduction of Fehling's solution by the urine was observed in some instances in the acute stages. Four clinical types of lesion were defined—namely: (1) vesiculo-pustular, (2) erythematous vesicular, (3) irregular scaling patches, (4) thick scaly patches with fissuring. All these types were superficial, localized, circumscribed in outline, very chronic, and very intractable. Attacks of an acute

type in which the vesiculo-pustular type of lesion predominated were described. The eruption might be localized, but in many cases it was widely distributed, or associated with a generalized eruption of lesions of the erythematous and scaly types. In these cases the same organism had been cultured from lesions on scalp, arm, and a nail. This type of case showed a yeast infection as a rule. Some of the cases were typical examples of cheiropompholyx, and in these no generalized eruption was observed. Infection of the nail was common in about one-third of the cases. The lecturer emphasized the great importance of recognizing the nature of these cases where the question of an occupational dermatitis was involved.

Dr. R. W. MacKenna gave a lantern demonstration of a large number of coloured pictures of skin diseases, with a running commentary on their characteristics, diagnosis, and treatment.

EXTRINSIC STRICTURE OF THE OESOPHAGUS.

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland on October 25th, with the president, Dr. J. Lait, in the chair, Dr. R. R. Woods read notes on the clinical signs of a case of extrinsic stricture of the oesophagus. Dr. J. Lait subsequently gave an account of the post-mortem findings.

A man aged 48, seen early in August, had suffered from dysphagia for two months, and could only swallow fluids slowly. He had glands on both sides of his neck and a lump, the size of an orange, in the right hypochondrium. The liver was enlarged and the spleen palpable. An *x*-ray examination revealed a mediastinal tumour and a stricture at the level of the seventh to the ninth dorsal vertebrae. Oesophagoscopy showed an extrinsic stricture 31 cm. from the teeth. The patient's teeth were removed; a gland sent for section was reported as suggesting the bare possibility of lymphosarcoma. The neck was subjected to treatment by means of *x* rays with fluorescein painting as described in the *British Medical Journal* of August 10th (p. 233). The glands seemed to remain stationary, but the patient had only one course of treatment before his death. The oesophagus was treated with radium by means of a special applicator which enabled fully screened radon (1.2 mm. lead) to be inserted while allowing a passage for liquids during treatment. He had two applications; fluorescein was given every second day by the mouth during treatment. Surface applications to the thorax were also employed. Although successive *x*-ray reports showed that the tumour was increasing the patient's swallowing improved rapidly, and he became able to take solid food.

The post-mortem examination showed two points of particular clinical interest: the fibrosis which had occurred where the radon was applied, and the desquamation of oesophageal epithelium round the position of the applicator. This seemed to be the result of a peeling dose rather than a radium burn. There was a large mediastinal tumour present which had occasioned the stricture of the oesophagus by external pressure; there was no intrinsic growth of the oesophagus. The tumour had infiltrated the right lung in a massive way, resulting in its collapse, and the right pleural cavity was filled with fluid. A large tumour mass was found in the situation of the head of the pancreas, and another large mass about the size of a foetal head involved the left kidney. The liver, spleen, and suprarenals were free from tumour nodules. The tumour was a lymphosarcoma. Sections cut from the site of the radium application showed fibrosis and retrograde changes in the tumour.

Dr. Cyril Murphy asked if the patient had had any symptoms referable to pancreatic disease or renal trouble, and what part of the body Dr. Lait regarded as being the primary site of the growth in this case.

Dr. V. M. Synge was doubtful whether tumours such as this were of an exceptionally malignant type. In this case the tumour apparently was exceptionally malignant, but he thought that as a rule tumours in the mediastinum were of the slow-growing type, in which *x*-ray treatment gave fairly satisfactory results; it made the patients much more comfortable, and prolonged their lives for some months at any rate.

Dr. T. T. O'Farrell referred to a similar case which he had seen some years ago—a lymphosarcoma in the mediastinum with secondary deposits in the kidney. He asked if there were any clinical symptoms in connexion with posterior mediastinal lesions, and if in the present case there was any cyanotic induration of the spleen.

Dr. R. H. Micks asked if Dr. Lait attributed the fibrotic change which had taken place in the specimen to the radium. It seemed to him a rather short time for such a change to have taken place.

Dr. Woods, replying, said that no special kidney tests had been performed, but, judged by ordinary tests, the urine was quite normal. Some posterior mediastinal symptoms were present; there was pressure on the vena cava, and about a fortnight before death the patient developed oedema of feet and legs, while shortly before death ascites set in. He thought that possibly the fibrotic changes in the tumour could be attributed to the radium. All through the radium treatment the patient was receiving fluorescein at the same time, but whether this had any effect on the efficacy of the radium treatment it was not possible to say.

Dr. Lait, replying, thought the primary growth was in the mediastinum. The spleen did not show any cyanotic induration. He believed that the fibrosis which had occurred was the result of the radium treatment. In a patient with lymphosarcoma, the average duration of life he would give was three months. He regarded lymphosarcoma as one of the most malignant conditions.

Cancer of the Stomach and Duodenum.

Dr. A. R. Parsons read notes on two cases of cancer of the stomach and one of the duodenum.

The first patient was a woman, aged 65, who was admitted to hospital about the middle of September; she was anaemic and emaciated, but stated that until a week previously she had been at her work, and feeling pretty well. She vomited incessantly, and a large tumour could be felt in her stomach; she died four days after admission.

Dr. Parsons expressed the belief that a malignant tumour of the stomach, so long as it did not invade the pylorus, did not cause very much inconvenience.

The second patient was a woman, aged 63, who came to the dispensary stating that her doctor in the country had sent her up to town to be *x*-rayed. Her only complaint was flatulence, but she said that two years previously she had lost the sight of one eye, and thought that since then her health had not been so good as previously. A small tumour could be felt lying across the mid-line, freely movable. The liver was not enlarged, she had no pain, and her family history was good. After a test meal an extraordinarily high degree of total acidity was found, but no free hydrochloric acid.

Dr. Parsons stated that this case was considered to be one of carcinoma of the pylorus, but at operation it turned out to be a carcinoma of the body of the stomach.

The patient with duodenal cancer was a man, aged 30, who said he had had good health till March, when jaundice appeared and lasted for three or four days, after which he recovered and resumed work. In May he had another attack, and this time the condition persisted. He was admitted to hospital on August 28th deeply jaundiced, and suffering from intense irritation of the skin. There was no history of pain or vomiting. The urine contained a trace of albumin and a very large amount of bile pigment. The liver was slightly enlarged, and at times it was possible to feel an ill-defined tumour about the mid-line. The diagnosis lay between impacted stone in the common bile duct and malignant disease of the head of the pancreas. The Graham-Cole test showed the presence of a pathological gall-bladder.

Dr. Parsons remarked that he was more inclined himself to a diagnosis of carcinoma of the head of the pancreas. At the operation a greatly enlarged liver, extending nearly down to the level of the umbilicus, was found, and a distended gall-bladder, but no stones. Cholecystenterostomy was done, but the patient died the next day. This case proved to be not one of biliary calculus, but of carcinoma of the duodenum following an ulcer.

Dr. J. T. Wigham, demonstrating the specimens, said that in the first case it was curious that there had been so few symptoms before the patient was admitted to hospital, although on examination it was possible to feel the tumour. The stomach was hard and tough. The tumour did not quite reach the pylorus; it was a very scirrhous tumour, and bore out the idea that the main symptoms in the case were due to involvement of the pylorus; but the pylorus itself was not involved, and so there was no obstruction to food. Cancerous diffusion was extensive in the glands, and there was a small nodule in the liver. In the second case two pieces of the stomach had been taken away very near the one which proved to be malignant, and these two pieces had shown no signs of malignancy. A papillomatous mass blocked the pylorus, but sections had been cut since the operation, and there was no doubt from the general appearance of the cells that it was a cancer, an early specimen which probably followed an ulcer. In the third case the liver was bile-stained, and the intestine and the gall-bladder were filled with blood. The diagnosis of a tumour of the head of the pancreas was a very natural one

to make, as the mass was in just the position for such a tumour. The tumour was, however, a cancer of the duodenum, and showed the appearances usually associated with intestinal cancers.

Dr. T. GARRATT HARDMAN showed lantern slides of x-ray photographs illustrating Dr. Parsons's cases.

The PRESIDENT, referring to the case of cancer of the duodenum, said he was inclined to believe that the growth was malignant from the start, and was not secondary to peptic ulcer of the duodenum. Peptic ulcers of the duodenum were usually found near the pylorus, and they arose more commonly in the first stage; the present specimen was in the second stage. Dr. R. A. Q. O'MEARA remarked on the site of the tumour in the duodenum. He thought one reason for the frequency of cancer in the second part of the duodenum might be that toxins were excreted from the liver, and set up a process of ulceration in that region which went on to carcinoma. In cases of severe burns ulceration of the second part sometimes occurred, and was apparently due to secretion of toxins from the liver.

Dr. PARSONS, replying, said that it was difficult to know whether a stricture of the pylorus was fibrous or malignant. He was convinced from a clinical point of view that there was such a thing as a fibrous stricture. Dr. WIGHAM added that the tumour in the case of carcinoma of the duodenum seemed to him to be such an ordinary tumour of the intestine that he did not see any reason why it was not derived from the mucous membrane in the same way as tumours of the caecum were derived.

Cerebral Haemorrhage.

Dr. A. B. CLERY read notes on, and demonstrated a specimen of, a case of cerebral haemorrhage.

A man, aged 70, was admitted unconscious to hospital on October 12th. He had been suffering for two years from headaches and attacks of vertigo. The day before admission, when stooping down to tie his shoe-lace, he collapsed and became comatose. Examination showed that the arteries were hard and the blood pressure was 200; the heart was normal, and so were the plantar reflexes. He had incontinence of urine, and a specimen contained albumin and sugar. Cheyne-Stokes respiration was present. The patient died the day after admission, and at the post-mortem examination the dura was found to be densely adherent to the calvarium, while there was blood in the posterior lobe. A blood clot was found in the ventricles, particularly involving the right anterior horn. The third ventricle was widely distended, and the caudate nucleus disrupted.

Dr. Clery remarked that this was one of the few cases in which it was possible to show the exact site of origin of a cerebral haemorrhage, the lesion involving one of the branches of the anterior cerebral artery.

The PRESIDENT said that in cases in which there were secondary changes in the kidney the patient frequently died of cerebral haemorrhage. Dr. V. O. MCCONNICK said that it was difficult to know whether this was a diabetic or a nephritic case, but if the haemorrhage had spread into the fourth ventricle he thought it would explain the presence of sugar in the urine. Dr. J. A. MCGRATH discussed the reasons why the blood in these cases tended to track inwards towards the ventricles rather than outwards, and pointed out the importance of thrombosis preceding haemorrhage in bringing about this result. Dr. V. NATH discussed the Cushing phenomenon, and Dr. CLERY replied.

Pathology of Argyria.

Dr F. S. BOURKE showed a man suffering from argyria, who had been admitted to hospital on August 12th complaining of a sore throat and pains in his limbs. He had a history of syphilis, and so was sent to the venereal department, where his colour at once attracted attention. He stated that he joined the army in 1896, and contracted syphilis in 1897; he served in India until 1908. While there some of the men suffered from some throats, and he had seen them cauterizing their throats with silver nitrate, and did the same himself. He first used silver nitrate in 1908.

The PRESIDENT said he had never seen a case of argyria, and could find very little about the condition in the literature. It was now, he thought, very uncommon, but had been more common formerly, when silver nitrate was used for treating cases of gastric ulcer. Dr. CYRIL MURPHY stated that he had seen this patient on a previous occasion, and at that time the pigmentation had only extended as far down as the abdomen. Sir JOHN MOORE mentioned a patient, seen years previously, who was exactly the counterpart of the patient now shown as far as pigmentation was concerned. His patient had used silver nitrate for treating gastric ulcer, from which he suffered. Dr. R. A. Q. O'MEARA said that the silver was found not only in the skin, but also in the internal organs. The salts of heavy metals had the property of combining with albumin, and the silver in cases of argyria formed with albumin in the tissues an insoluble substance which was deposited between the cells, but not in the cells. He thought that the blue colour was more apparent in the face because of the relatively greater blood supply to the skin of the face as compared with the skin of other parts of the body. Dr. E. T. FREEMAN said that in India silver nitrate had formerly been used as an astringent in dealing with tropical diarrhoea. He thought that possibly this patient had had some silver for the treatment of this condition while serving in India, as well as what he had used himself for cauterizing his throat.

OPHTHALMOLOGICAL INSTRUMENTS.

A MEETING of the Optical Society was held at the Imperial College of Science and Technology, South Kensington, on November 14th, with the president, Mr. F. TWYMAN, F.R.S., in the chair. Mr. A. G. FREWIN of the Emil Busch Optical Co., Ltd., gave a short demonstration of two ophthalmological instruments.

Mr. Frewin dealt first with the Busch optometer, designed by Professor Thorner, an instrument for defining objectively the errors of an ametropic eye. By it could be measured in dioptres the hypermetropic or myopic error of a symmetrical eye, or the ametropia in the two meridians of an astigmatic eye, together with the directions of the two meridians. The patient directed one eye into the exit pupil of the instrument while the observer looked into the eyepiece and focused on the patient's macula the image of the straight filament of a small electric bulb. The focusing head moved a scale relatively to a fixed pointer, so that when the side edges of the filament were sharp the ametropia could be read off at once. Freedom from glare and corneal reflections was secured by two suitably arranged semicircular stops, which ensured that the illuminating rays were incident on the top half of the patient's cornea, while the light reflected from the fundus, which reached the observer, issued from the lower half of the cornea. The patient's eye was adjusted so that the instrument measured the vertex power of the proper corrective lens when its vertex was placed 12 mm. in front of the patient's cornea.

Mr. Frewin then described a glare-free, reflexless, stereoscopic hand ophthalmoscope, designed by Professor Thorner. In the new instrument mirrors were used for illuminating the fundus and for reflecting its image into a binocular eyepiece so that the magnified image was seen in stereoscopic relief. The fundus was illuminated by an image of the source of light focused on the lower half of the patient's cornea by a concave mirror. The optical system was such that the centres of the observer's pupils were conjugate with two separated points situated on the patient's cornea above the image of the source of light. The rays from the retina which passed through the right of these two points could only reach one eye of the observer, and those which passed through the left point could only reach the other eye; consequently, the two eyes appeared to see the retina from two points of view, and it was therefore seen in stereoscopic relief. Rays reflected from the patient's cornea could not enter the observer's pupils.

Mr. E. F. FINCHAM then described and demonstrated his "stereo-fixation device for campimeters." He said that in this device one eye was fixed on a stereogram at the centre of a chart being viewed, while the other was fixed on a stereogram which was reflected into it by means of a right-angled prism arrangement. When the two stereograms were combined the eyes were in proper adjustment for viewing the chart.

The meeting concluded with the exhibition of Messrs. Bausch and Lomb's 3 reel, 16 mm. moving-picture film illustrating the manufacture of optical glass.

Reviews.

MEDICAL WOMEN IN INDIA.

A recent book with this title[1] contains a most valuable account of the work done over a period of sixty years by medical women in India. It is a lucid record, distinguished by its fair and moderate expression. By its restraint it gains in effectiveness, and it leaves the reader with the conviction that medical women, in face of an overwhelming amount of work, have been unnecessarily hampered in their task by the prejudice of some of their own compatriots. Lack of imagination sometimes prevents those in authority from realizing that professional workers—women as much as men—in insisting on a proper status, adequate pay, and suitable conditions of work, are not merely fighting for their own position, but also to ensure that the work done may be the best possible and of the greatest benefit to those to whom it is rendered. When so much was waiting to be done and there were so few to do it, it is disheartening to read of the way in which the efforts of the pioneers were sometimes thwarted. Although there was frequent lack of understanding on the part of those who might have done so much to help, there were, however, many notable exceptions, and to these the authors of *The Work of Medical Women in India* render grateful thanks. For a full list reference must be made to the book itself, but readers of the *British Medical Journal* will be gratified to find amongst them an honoured member of the Council of the British Medical Association—Colonel O'Kinealy.

The book opens with a review of the social conditions of the women of India, thus indicating the problems to be dealt with when organizing efforts to improve their health. Then follows an account of the work done by the pioneer medical women, and it is interesting to note the close fellowship between British and American medical women, and also the prominent part taken by the missions of both countries. It is a matter for congratulation that the Countess of Dufferin's Fund owed its origin to Queen Victoria. Dr. Elizabeth Bielby and Dame Mary Scharlieb had been received by Queen Victoria at various times, and on one occasion the former presented to the Queen a locket from the Maharani of Punna, containing a petition that she should take steps to help the women of India in sickness. Queen Victoria specially charged the Countess of Dufferin—when Vicereine of India—to do something in the matter, and the result was the formation of the Countess of Dufferin's Fund. Since then it has been the honourable tradition of the Vicereines to pay special attention to the means of relieving illness amongst the women of India. The several funds thus initiated have, in the course of years, been used not only to supply the services of medical women, but also for special work in connexion with maternity cases, child welfare, and the training of midwives. These activities have proved of great value, but have confessedly only touched the fringe of the problem. The population of India is so large that many millions of women, particularly in the country districts, are still unable to obtain suitable advice and treatment; and preventive medicine, particularly with regard to domestic hygiene, is still in a primitive stage in most districts.

The reader gains from this book (which concludes with a map showing the centres where medical treatment for women is available) not only an interesting account of the work done hitherto, but also a conviction that our duty is not yet fulfilled. The question is not solely, or even primarily, one which concerns medical women, but the British nation as a whole in its relation to India. There are, in that country, vast numbers of our fellow subjects suffering pain and disease, much of which is obviously preventable. Owing to the social customs of the sufferers, assistance can be rendered most efficiently and promptly by medical women, and surely it is the duty of the British nation to see that this assistance is made available for them. On account of the present transitional state of the Government of India help can be most effectively organized by the central administration. By no other means can a suitable personnel of sufficient numbers and experience be obtained, or can they be supplied with the necessary accessories and apparatus to make their work of good effect.

Organized efforts in India would be greatly strengthened by an expression of public opinion in England, and it would seem that knowledge of the facts is all that is needed to arouse the people of this country to a realization of our national responsibility in the matter. A committee, consisting of Indian and British medical women who have served in India, started by Lady Barrett and the Lady Sybil Smith, and affiliated to the Medical Women's Federation, has been recently formed to deal with the subject; and an appeal might be made to the newly enfranchised women of England to make this matter one of the first on which to exercise their political influence. Surely it is not too much to hope that when the quickest and most efficient means of alleviating so much suffering is understood the whole British nation—for it is not a question concerning women only—will demand the formation of a service of medical women for India, which shall be under Government auspices and have such conditions of service and pay as will attract women of the best type. This book should go far to stimulate such a demand.

Christine Murrell.

MODERN METHODS OF TREATMENT.

A weighty supplement to the George Blumer Edition of the *Billings-Forchheimer Therapeusis of Internal Diseases*[2] brings into the hands of those who own or consult the six-volume encyclopaedic work of that name all that is important in recent therapeutic advances. The main body of the work was reviewed in our columns on January 10th, 1925 (p. 77), and the present volume contains 57 monographs intended to bring up to date the exhaustive original articles. In the preface it is stated that "in very few instances have original authors found occasion to emendate or modify their articles written in 1924," but, of course, the advances that have followed the introduction of such remedies as insulin and liver receive full notice. Notwithstanding the editor's avowed aim of making the volume a supplement, many of the articles are really complete reviews of the present status of therapy in the several fields of medicine. The chapters on the vitamins, syphilis, hypotension, cirrhosis of the liver, and diseases of the heart and pericardium are complete and self-contained.

It is difficult from a volume of such varied contents, all equally erudite, to single out one topic for comment, but the monograph on the treatment of thrombo-angiitis obliterans will serve as an example of the fare provided. The author has seen and treated several hundred cases. He fixes dogmatically on an etiological factor—namely, tobacco poisoning in a specially sensitive individual—and reminds the reader that the disease is subject to spontaneous relapses and remissions, whose occurrence may render difficult the task of assessing accurately the value of whatever may be the therapeutic procedure adopted. He proceeds to describe a mechanical diagnostic device by whose aid the physician may arrive at a prognosis and a decision about the type of treatment best suited to the patient under examination, and suggests a rational, practical, and efficacious line of treatment which, stated briefly, consists in making repeated injections of hypertonic salt solution into the general circulation, whereby the blood volume is increased and the vascular channels are reopened. The fullest technical details, ample statistical tables, and a consideration of the contraindications and adjuvant measures close a pithy review.

[2] The George Blumer Edition of *Billings-Forchheimer's Therapeusis of Internal Diseases: Supplement.* New York and London: D. Appleton and Co. 1929. (6½ × 10, pp. xxxviii + 760; illustrated. 30s. net.)

Many of the 57 chapters are written by men well known in Europe as accepted authorities in their particular line of work. Professor Minot writes on the treatment of anaemia; Professor Stokes of Philadelphia on the treatment of syphilis; Chevalier Jackson on diseases of the oesophagus and on bronchoscopy in the treatment of pulmonary diseases; and Dr. Marine supplements his former articles on the thyroid gland. In addition to these outstanding articles there are several on topics not often fully presented to the practitioner; among these, of special interest is a summary of the whole subject of convalescence and an article on the treatment of the cancer patient as apart from the treatment of the cancer itself. Each chapter contains a full bibliography, and the volume is elegantly printed and well illustrated.

COLOUR AND COLOUR THEORIES.

THERE are few subjects in the whole of biological science which have excited so much controversy as that of colour vision: and one of the most belligerent and outstanding figures in the scientific battle has been CHRISTINE LADD-FRANKLIN. In the latter part of the nineteenth century two rival theories of colour vision were generally recognized as alternative candidates for priority—the three components theory of Young and Helmholtz, and the opponent colours theory of Hering. It cannot be claimed that either of these explains all the facts, or that one or the other will be permanently accepted as expressing the final exposition of the subject: the two are irreconcilable, and each one to a certain extent explains phenomena which the other leaves unexplained or deals with so inadequately as to be manifestly incomplete. At the International Congress of Physiology in 1892 Mrs. Ladd-Franklin criticized them both freely, and propounded a third theory, which she termed "the molecular dissociation theory," and ever since that date, up to 1926, she has written and published papers developing it. In a volume, *Colour and Colour Theories*,[1] these papers are gathered together, and these collected writings, while they contain nothing new, and although they suffer somewhat in their arrangement by a lack of logical sequence and involve a great deal of repetition, undoubtedly form the most authentic source of information for the study of her views. Whatever the imperfections of her theory—and no critical reader can deny that they exist—her work merits attention and careful study.

The essential feature of Ladd-Franklin's contribution to the question is to consider colour primarily in the light of the development of the colour sense. In the first stage of evolution light of any wave-length produced one response—white. In the second stage this single response was divided into two, one aroused by the long waves producing the sensation of yellow, the other by the short waves producing the sensation of blue. In the third stage the yellow response was further differentiated, producing the sensation of red for the longer waves and green for the shorter. Accordingly, when red and green are combined they revert to the more primitive yellow response, and when yellow and blue are combined they revert to the still more primitive white response. The periphery of the retina is still in the first stage, the intermediate zone in the second, and the central area has reached the third. When the central area has not evolved beyond the second stage a red-green blind individual results: when the entire retina remains in the first stage a totally colour-blind individual results. As to the mechanism of these sensations, Mrs. Ladd-Franklin argues that since yellow has no psychological relation to a mixture of red and green, or white to a mixture of blue and yellow, the combination must take place below the level of consciousness—that is, it must take place in the retina and be photo-chemical in nature (herein she differs from the Helmholtz theory). The response is due to the dissociation of a mother substance the cleavage products of which initiate nerve currents to the brain: in the red- and in the most primitive stage of a single white sensation, as occurs in the extreme periphery of the retina, and in the totally colour-blind, a single cleavage product is split off. In the second stage two cleavage products are capable of being split off according to the length of wave, and these produce respectively the sensations of yellow and blue. If, however, they are both split off at the same time and in the same concentration they immediately unite chemically and form the original single product, the vital response to which is white. Similarly, in the third stage three cleavage products may be produced, provoking responses severally of green, red, and blue; and since red *plus* green equals yellow, and yellow *plus* blue equals white, they may unite chemically at the periphery to produce a single sensation of white.

Although the theory in its general outline has many fascinating aspects, like all other theories it has its weaknesses. Two points may be mentioned. The explanation of simultaneous contrast, which depends upon a "retinal circulation" so rapid as to transfer molecules almost instantaneously through a finite distance, is somewhat far-fetched. A difficulty also arises with regard to the status of black, which is regarded as a state of non-excitation from the external world, a convenient arrangement to fill up lacunae in the retinal spatial field which otherwise would be disturbing. On the other hand, according to the theories of both Helmholtz and Hering, black is regarded as a sensation, being physically the opposite of the process of producing white; when the sensation of black is experienced it is indicative of stimulation of the cortex. Mrs. Ladd-Franklin is a psychologist, and certainly it seems that the psychological aspect of colour vision has been the most neglected in the past; it may perhaps in the future contribute in no small measure to a rational understanding of one of the most elusive and fascinating problems of science; but that understanding has yet by no means arrived.

A TEXTBOOK OF BACTERIOLOGY.

THE third edition of KENDALL'S *Bacteriology: General, Pathological, and Intestinal*[1] opens with a logically arranged account of the morphology and metabolism of bacteria, and proceeds to some chapters of a general nature on infection, immunity, and anaphylaxis. The author's recommendations in the sections on the culture of micro-organisms, the various staining methods, and other technical procedures are clearly derived from considerable practical experience. The specific pathogeny of bacteria and the methods for their detection are described amply, yet concisely: the book is thus not only a digest of present-day bacteriology, but an invaluable laboratory manual. Kahn contributes a section upon the reaction which goes by his name, and makes the point that his test, which is widely used in America, is at least as valuable as the Wassermann test and much simpler in practice. The volume includes a well-balanced description of such developing subjects as the filterable viruses and bacteriophage, and some excellent notes on the Dick test.

The word "intestinal" in the subtitle is justified by the inclusion of information, both practical and academic, on the bacteriology of the normal and the diseased alimentary tract. The author mentions the fact that certain organisms produce absorbable toxins in proportion to the amount of protein they metabolize, whereas in dealing with carbohydrates they produce rather the non-toxic lactic and other acids. The practical application of this knowledge consists in the provision of so much carbohydrate in the dietary that the production of harmless acids is encouraged while proteolysis and toxin production is minimized. Some favourable clinical results in typhoid fever have been attributed to the use of a high calorie diet rich in lactose.

On a number of matters that are still under investigation—for example, the question of the unity or plurality of the streptococcus-pneumococcus groups—the author gives a commendably impartial statement of opposing views. His textbook, in this as in other respects, is excellent.

BODILY EFFECTS OF EMOTION.

THE second edition of *Bodily Changes in Pain, Hunger, Fear, and Rage*,[1] by Professor W. B. CANNON, is practically a new book, for the first edition appeared fourteen years ago, and has been rewritten in the light of the very extensive amount of work that has appeared since then on this subject. Professor Cannon's department has provided a considerable proportion of this new work, for a list of researches published at the end of the volume includes twenty articles published by the Physiological Laboratory of the University of Harvard during the past decade. The first half of the book deals with the factors regulating the liberation of adrenaline by the suprarenal glands. This question has been a matter of acute controversy for several years, but Professor Cannon is able to show that the most recent evidence is clearly in favour of his view that the secretion of adrenaline is augmented by the emotions. The evidence in support of this view comes not only from his own department, but also from France and various other countries. The author analyses in turn all the effects produced by increased adrenaline secretion—namely, the rise in blood sugar, improvement of contraction of fatigued muscle, acceleration of blood coagulation, increase in red blood corpuscles, etc. The utility of bodily changes in pain and in emotion is next considered, and this is followed by chapters on the nature of hunger and thirst. In conclusion, Professor Cannon discusses the various physiological and psychological theories which have been formulated to explain the nature of the conditions. The last chapter is entitled "Alternative satisfactions for the fighting emotions," and here the author suggests international games as an alternative to militarism. Reference is made to the way the inhabitants of the Pacific Islands have substituted baseball or cricket for head hunting. The general line of argument in this chapter seems, however, somewhat unreal, for it is hard to believe that many people now regard war as a valuable school for the virtues.

NOTES ON BOOKS.

DR. JOHN H. EWEN'S object in his *Aids to Psychology*[2] is to present in concise form the main facts of this science for the use of students. The author has especially the needs in mind of those who are aspiring to a diploma in psychological medicine. The book is ably compiled, and, in view of the lack of uniformity in terminology, and, in consequence, the difficulty of preparing for examinations, it cannot fail to be of practical service to the student. The more academic aspects of the subject are summarized, and no attempt is made to deal with the complexities of the "new psychology." In any case an academic foundation in psychology is most desirable.

The third volume (Echinokokkenkrankheit-Gelenkerkrankungen) of the new German dictionary of practical medicine,[3] edited by Professors GEORG and FELIX KLEMPERER, has closely followed its predecessor, to which we drew attention some months ago (July 13th, 1929, p. 55). Among the thirty-seven articles in the present volume attention may be drawn to those on lethargic encephalitis, by Professor C. von Economo of Vienna, who gave the disease its name; endocarditis, by Professor Paessler of Dresden; enteroptosis, by Professor H. Strauss of Berlin; epilepsy, by Professor Rosenfeld of Rostock; typhus fever, by Professor Jurgens of Berlin; fractures, by Professor M. Kirschner and Dr. G. Ellmer of Tübingen; cerebral abscess and cerebral tumour, by Professor H. Pette of Hamburg; and yellow fever, by Professor H. da Rocha Lima of S. Paulo, Brazil. The work as a whole maintains the high standard of the two previous volumes.

In *A Short Course on Human Osteology*[4] Professor DRENNAN of the University of Capetown presents clearly and accurately the main facts of the subject. It is obviously impossible nowadays to show much originality in a purely descriptive account of the bones, such originality as is possible being largely limited to the manner in which the facts are arranged. The work differs from most modern anatomical textbooks in the entire absence of illustrations, their place being taken by blank pages, the idea evidently being that the student should make his own illustrations—a very laudable procedure, but one which we fear it will not be easy to persuade the student to follow. The book, within the limits imposed by the author, is almost above criticism, but we doubt whether the statement that the incus is developed from the first arch and the stapes from the second is in accordance with recent investigation. We think it would be better, instead of saying that a cervical rib presses upon the lower trunk of the brachial plexus, to say the trunk presses upon the rib; and we should have liked, in the discussion on the growth of bone, to see some reference to the contribution which the growing mandible makes to the elucidation of the problem. The book, which is of pocket size, can be warmly recommended to students requiring in small compass the essential facts of the subject, and who have a penchant for making their own diagrams.

Many of our readers will no doubt be familiar by now with Dr. J. E. CHEESMAN'S *Synthetic Anatomy*,[5] several parts of which have already been reviewed in these pages. Parts iv, v, and vi, which have now been issued, are concerned with the anatomy of the leg and foot. In them Dr. Cheesman follows the method which he may be said to have introduced, displaying the same ingenuity and achieving the same high standard of accuracy. The skill with which he brings the back of the leg and the sole of the foot into the same plane is particularly noteworthy. As we have said before, there are several ways of studying anatomy; Dr. Cheesman's way is one, and there is no reason, financial or otherwise, why the method should not be given a fair and patient trial.

A Short Introduction to Human Anatomy[10] is a pamphlet of fifteen pages with eleven full-page illustrations. It is intended for nurses, members of ambulance corps, and students of physical culture, and to such it will no doubt be of considerable interest and assistance.

Professor C. B. JORDAN'S short textbook on *Qualitative Analysis*[11] has been written for students of pharmacy and of medicine, and sets out to emphasize all the points where qualitative chemical analysis may have a direct application to practical pharmacy and medicine. The volume is divided into four parts. In the first of these the student, who is supposed to have already had a grounding in chemistry and physics, is introduced to the general terms and chemical conceptions that are likely to be useful to him in the course of his analytical studies. The second and third parts deal with the bases and the acids most often met with in chemical analyses. The book is clearly written, and should be of service to those demanding a somewhat specialized account of the subject with which it deals.

MUNBY'S *School Laboratory Fittings*[12] describes the general considerations governing the choice of a scheme of fittings for science rooms. It is written by an architect and will prove useful to architects, but it is intended more particularly for science masters, who, although they may know quite well what services they require, often fail to foresee in their own design a defect that will emerge after construction. The author has made a special study of the needs of schools and colleges, and is well acquainted with the kinds of trouble and inconvenience that arise from faulty arrangement and construction. A chapter deals separately with the requirements of each of the subjects of physics, chemistry, and biology, and describes the fittings needed for lecture rooms and laboratories, with attention to moderate desires as well as more extensive provision. Other chapters deal particularly with ventilation, gas, electricity, water, and drainage. The details have been carefully considered and minutely described, even to the arrangement of cupboards and drawers, and the choice of wood best suited to different purposes. It is true, as the author remarks, that some people, including very intellectual and experienced bodies, never really crystallize their ideas until the architect has worked out quite a number of schemes, which wastes time and is discouraging. The book should therefore be particularly useful to the heads of schools and colleges, and should be consulted by all who may have in prospect the alteration or new construction of science rooms.

IMPERIAL CANCER RESEARCH FUND.

ANNUAL REPORT FOR 1928-29.

The twenty-seventh annual report of the Imperial Cancer Research Fund, which has just been published, covers the year 1928-29. Renovations in the laboratories have been effected at a cost of £480, and it has been decided to purchase radium with a view to further experiments on the treatment of tumours in animals. Hitherto the radium employed has been in the form of a radium applicator, belonging to Dr. J. C. Mottram. Sir George Makins, the honorary treasurer, points out that the income from investments amounts only to about £8,000, so that the fund is still dependent to a large extent on the annual grant of £2,000 from Lord Atholstan, which terminates in three years' time, and on subscriptions and donations. The expenses of research during the year under review amounted to £13,445.

Director's Report.

Dr. J. A. Murray, F.R.S., director of the fund, reviews the work in the laboratories during the year, and mentions that it is proposed to include regularly in future reports such comments on various aspects of cancer research as have appeared sporadically in previous years. The present report contains a critical commentary by Dr. W. Cramer on experimental carcinogenesis.

During the current year Dr. Cramer has published the results of an investigation indicating that the development of carcinoma is not solely dependent on changes in the epithelial cells; he believes that local inhibitory factors exist, and that malignancy follows interference with these. The nature of the tissue elements in the skin responsible for this resistance to malignant change is still speculative, but attention is called to the possibility of the wandering cells of the connective tissue being concerned. The process of carcinogenesis would seem then to consist of two phases: a condition of "potential malignancy," kept in check by local resistance; and a local breaking down which permits the immediate development of the hitherto potentially malignant cells.

The continued study of fowl tumours at the Stroud Farm laboratories has yielded two interesting results. We have previously referred to Dr. A. M. Begg's work on a spontaneous tumour in a fowl, which could be transplanted by living cells, and appeared microscopically as a *fibroma*. Owing to its power of metastatic growth it was described as a fibrosarcoma in a paper published in 1927, but, after having maintained this character during propagation for two years, it manifested a striking change; it grew more rapidly, became softer and more cellular, and for the first time it was possible to prepare an extract of it. When the filtered cell-free extract was injected into fowls new tumours originated, and thus it was clear that a marked biological alteration had occurred in the direction of increased malignancy, with possibly the development for the first time of filterability. It seems likely, therefore, that it has been shown that a filterable tumour may evolve from a non-filterable, relatively benign neoplasm. The second interesting result was due to a joint investigation by Drs. Begg and Cramer of the statement that transformation of normal into malignant cells had been effected by the action of such simple chemical substances as arsenious acid, indol, and skatol. These two investigators, however, secured evidence that an uncontrolled factor was responsible for this transformation, and that this factor was probably an unsuspected contamination with the virus of the Rous sarcoma, which can sometimes exhibit an unexpected virulence. Thus the positive results recorded in the literature as examples of such transformation may have to be discarded as experimental errors.

Mr. H. G. Crabtree has continued his study of the metabolism of cancer cells, using Professor Warburg's method; he has now begun to investigate the metabolism of irradiated cells. Dr. R. J. Ludford, employing the *intra-vitam* acid dye, trypan blue, has shown that living tumour cells take up this stain only very exceptionally, whereas necrotic areas of tumours become diffusely coloured. Collections of deeply stained macrophages were found at the margins of many tumours, but they were strikingly absent round secondary growths in the lungs. This raises the question whether the action of metallic colloids on cancer is exercised indirectly through the macrophage type of cell. Attention has been given to the modification, by Dr. A. T. Todd of Bristol, of Professor Blair Bell's *colloidal lead treatment*. It is stated that the possibility has been conclusively proved of bringing about the disappearance of some definitely malignant tumours by the intravenous injection of certain colloidal lead preparations. This result could be obtained only in a percentage of the cases so treated, and in certain instances in which regression of the primary tumour was noted some of the metastatic growths proved resistant. The clinical results obtained by Dr. Todd suggest that the action of the lead colloid is probably not a direct toxic one, but that a more complicated mechanism is concerned. It is suggested that the way is perhaps opening for improvement of the therapeutic effect of such lead preparations. There is already considerable evidence to show that the lead colloid is segregated and accumulated in macrophages and other *phagocytic cells throughout the body in the same way as* are colloidal dyestuffs.

Experimental Carcinogenesis.

Dr. Cramer reviews the systematic investigation of the experimental production of cancer in the last ten years. The work of Fibiger, in 1914, suggested that chronic irritation was the cause of the gastric cancer in rats due to the presence of a particular nematode. Similar tissue changes were observed in the case of other parasites, but the results were so irregular that the value of this method of investigating carcinogenesis was not generally recognized until 1921, when it was adopted in laboratories all over the world. Two main lines of research were followed: one concerned with the various cancer-producing agents, and the other with the reaction of the organism to a given cancer-producing agent. Progress along the former of these lines brought into prominence occupational cancer, which was at first considered little more than a scientific curiosity, but the experimental demonstration of carcinogenesis resulted in epitheliomatous ulceration of the skin contracted at a factory or workshop being added to the list of compulsorily notifiable industrial diseases. Dr. Cramer recalls the discussion on occupational cancer at the Annual Meeting of the British Medical Association in 1922, at Glasgow. Four years later a departmental committee, appointed by the Home Secretary, reported in favour of the view that mule-spinners' cancer was an occupational disease. With the further discovery that all lubricating oils were not carcinogenic, and that the property might be removed by suitable treatment, this form of cancer became a preventable disease. No single chemical substance was isolated as being responsible for the carcinogenic effect. Certain physical agents, such as the rays from a mercury vapour lamp and prolonged sunlight, were also shown to be carcinogenic. Dr. Cramer remarks that most of the subsequent work in laboratories has been directed rather to the reaction of the organism to these agents, and considerable progress has been made. One outstanding result has been recognition of the fact that prolonged chronic irritation is necessary to induce cancer. No increase in the degree of chronic irritation, or combination with it of a mechanical injury, has rendered it possible to induce cancer rapidly within the space of a few weeks. Dr. Cramer comments on the "age incidence" of cancer, and shows the importance of bearing in mind the difference between the normal duration of life in such an animal as the mouse, and in man. This consideration suggests that the period of induction in the human subject is between 7.5 and 9 years, or, in the case of continued tar-painting, the figure applied to man would be 15 years. It is significant that the study of occupational cancer in man has shown that a malignant growth hardly ever appears until

seven years have elapsed since the occupation was commenced, and that most cases develop malignancy about the fifteenth year. The important conclusion is drawn that cancer arising at the age of 45 in the stomach, or breast, or uterus owes its origin, probably, to a slow-continued process which began some ten or fifteen years before, and not to some event immediately preceding the appearance of the growth. Dr. Cramer recalls the fact that, in the previous annual report, an international comparison of all organs with regard to the incidence of cancer indicated the existence of a mysterious law of compensation. Whenever in one country there was a markedly lower incidence of cancer in one organ, there was a correspondingly higher incidence in one or more other organs. Illustrations are given of the working of this law in respect of Japan, Holland, and England. The net result, he adds, appears to be that the total mortality from cancer is approximately the same in the different countries, although the organ incidence varies greatly. A compensating factor at work is, he states, susceptibility, which determines the number of people who, under average conditions, will develop cancer. He draws the practical conclusion that if this is so important a factor as appears probable, then freedom from cancer is more likely to be attained by diminishing the susceptibility to it than by trying to hunt down the various forms of chronic irritation to which human beings are exposed. The next step in the experimental study of carcinogenesis would be the investigation of the factors determining this susceptibility. So far all experiments along this line happen to have affected the susceptibility in such a way as to increase it, but, since this factor can be affected experimentally, it is obviously possible to diminish it, and the significance of such a step would be very great.

TRAINING AND EMPLOYMENT OF MIDWIVES.

THE CENTRAL MIDWIVES BOARD AND THE DEPARTMENTAL COMMITTEE'S REPORT.

IN the *Journal* of September 28th (p. 592) we gave a full account of the report[1] by the Departmental Committee appointed in 1928 by Mr. Neville Chamberlain as Minister of Health "to consider the working of the Midwives Acts, 1902 to 1926, with particular reference to the training of midwives (including its relation to the education of medical students in midwifery) and the conditions under which midwives are employed." It will be recalled that one of the three principal matters dealt with in the body of the report was the composition and functions of the Central Midwives Board. An acute and important difference of opinion arose within the Departmental Committee in regard to two of the functions at present exercised by the Board—namely, approval and inspection of training institutions and teachers, and determination of the conditions of entry into the calling and the length and character of the training to be undergone. The majority of the committee proposed that these functions should be transferred *en bloc* to the Minister of Health, who should have the assistance of an advisory committee. Two of their number, however, Dr. J. S. Fairbairn and Mrs. Bruce Richmond, dissented strongly from these conclusions in a joint reservation appended to the report.

The Central Midwives Board for England and Wales has now issued two documents by way of reply to the Departmental Committee's report and recommendations. One is entitled "Observations," and the other "Memorandum," and each is published at the price of 6d. by Spottiswoode, Ballantyne and Co. (1, New Street Square, E.C.4). In the former the recommendations of the Departmental Committee and the observations of the Board are set out in parallel columns, for convenience of reference: the latter covers much the same ground, but is more explanatory. For our purpose it will suffice to refer briefly to the memorandum, a pamphlet of twenty pages.

The memorandum first outlines the present constitution and duties of the Central Midwives Board, and the opinion is expressed that it is now "a thoroughly representative body to which the midwives, the medical profession, the local authorities, and the medical officers of health all send members." While, however, most of the representatives nominated by the other bodies concerned have remained members for many years, to the great advantage of all concerned, "it is a matter for regret that the Ministry of Health has frequently altered its nominees, and still more so that the eminent persons nominated are often unable to attend the meetings . . . owing to pressure of other duties." To the suggestion by the Departmental Committee that the number of members of the Central Midwives Board should be reduced the Board replies that this could only result in under-representation or non-representation of interests which are properly concerned. Of the report as a whole it says:

> "Much of the matter contained in the report of the Departmental Committee, and many of the recommendations therein, if read by persons without special experience would give the impression that suggestions are being made which are novel in character, whereas, in fact, many of them have been an essential part of the policy of the Central Midwives Board for many years."

This point is elaborated in a succession of paragraphs dealing respectively with provision for a comprehensive maternity scheme, improved midwifery services, the training of midwives, post-certificate training, and regulation of the practice of midwives; and the action taken, or contemplated, by the Board is indicated at various places. In regard to institutions for the training of midwives the memorandum states:

> "The Central Midwives Board objects in the strongest possible manner to those recommendations of the Departmental Committee which suggest the transfer of the duty of approval and inspection of training institutions and teachers from the Board to the Ministry of Health. It has read the reservations in the Committee's report (signed by Dr. J. S. Fairbairn and Mrs. Bruce Richmond) which deal with these recommendations, and entirely endorses them."

After quoting at length from the reserved report of Dr. Fairbairn and Mrs. Richmond, the Board emphasizes certain matters which lie at the root of its objection to the recommendation by the majority of the Departmental Committee that the power of approval of training institutions and teachers should be transferred to the Ministry of Health. It remarks, *inter alia*, that inspection of training and teaching is a wholly different thing from the inspection carried out at present by the Ministry's inspectorate, and that this inspection demands very different qualifications. It maintains that control of teaching, as in the case of medical education, should be entirely in the hands of a representative body of experts and not of a Government department.

> "The knowledge of what goes on in training institutions, which is obtained from evidence given at the hearing of penal cases and from information obtained as the result of conducting examinations, is invaluable, and could hardly be obtained in any other way."

Lastly, the memorandum expresses strong doubt whether the appointment of an advisory committee, as suggested by the Departmental Committee, would achieve the desired result, and observes that no valid reason is given for transfer to the Ministry of the power of framing rules as to training:

> "The Central Midwives Board is unaware of anything in the evidence given before the Committee which shows that the Board has not carried out its duties in this respect in a satisfactory manner."

In conclusion, the Board places on record its hope that those recommendations of the Departmental Committee to which it takes exception will not receive legislative sanction.

Nova et Vetera.

ON THE STIMULUS GIVEN BY RELIGION TO SURGERY DURING THE THIRD EPOCH OF THE NEOLITHIC PERIOD.*

BY

T. WILSON PARRY, M.A., M.D.Cantab., F.S.A.

Man, in his earliest state, can have been but little more than a mere animal. From this dim horizon in the far-distant past up to the beginning of the Palaeolithic period, a stretch of time covering incalculable millennia and known by the name of the Eolithic or pre-Palaeolithic period, little is known of him save that he must have been slowly, laboriously, but persistently working his way upward from the abyss of ignorance whence he had sprung to the level he had reached when the Palaeolithic period opened.

Then came another enormous expanse of time, the Palaeolithic period itself, before man could win for himself that higher grade of intelligence which marked him out, at the end of this period, as a skilful fashioner of flint implements and a remarkably fine artist for so early a date.

Yet another lapse of time, on this occasion probably only some eight thousand years, before we arrive at the term to which I wish to draw attention—namely, the third or final epoch of the Neolithic period. This epoch, while being memorable for its exquisitely flaked and polished implements, the introduction of pottery, and the development of agriculture, will be always deservedly distinguished by two outstanding features: (*a*) the commencement of architecture, embodying the building of massive tombs and gigantic open-air temples; (*b*) parallel with this achievement is found a much more astonishing innovation, and, strange to say, it is surgery that becomes enriched by the selfsame impulse that produced those fine architectural creations I have just mentioned. Both these elements of progress were actuated by a new and intense intuitive instinct for religion. There is no doubt that before this intuitive force had begun to take effect surgery was in an extremely primitive state—in fact, in much the same condition as we find it to-day among peoples still in their age of stone-culture.

The daring experiment of making a hole in the living skull of man was not the result of a gradual evolution of the art of surgery, but was a sudden jump forward of so startling a nature that one could hardly conceive its ever having been attempted in those early days had not the unseen force of religion made itself powerfully felt by the initiation of a rite that necessitated a surgical procedure far in advance of the instinctive surgery of the time.

One feels that had it not been for the creation of this religious ritual no attempt at cranial surgery would have been instituted until many centuries later. But the very fact that the spiritual condition of the time demanded this surgical effort being made to bring about the elimination of evil spirits paved the way for operations being performed upon the skull for disease of the cranial bones themselves.

Those massive stone constructions called by the name of dolmens, sepulchres of Neolithic man of the third epoch, many of whose skulls bear definite proof of operation, together with the holed skulls themselves, necessitate a prolonged study, and can therefore only be touched upon in this present paper. The importance attached to these findings is that they clearly date both the operation and the implements employed in performing it, and that this all took place before 2000 B.C., the year about which the great Stone Age ended for Northern and Western Europe. It is a strange thing, but nevertheless undeniably true, that this operation was only carried out during this third or Carnac epoch of the Neolithic period, and during that time was associated with the religion of this race of men, and not as an ordinary surgical procedure.

A differential diagnosis has been carefully prepared concerning the various holes discoverable in the skulls of prehistoric man. From these specimens, such as exhibit signs of the ritualistic operation can be easily singled out, and their characteristics can be briefly described. First, the site of the operation is always on healthy bone, and, indeed, the whole bone of the skull usually shows a normal and healthy appearance. There is no sign of injury or fracture such as one might find in the Inca or prehistoric Peruvian skull, nor do we find any trace of disease in the bone itself. Secondly, the hole, the lumen of which is usually either circular or oval, will be found to be funnel-shaped, having been bevelled at the expense of the external table of the skull by the scraping of the bone by flint flakes. The sides of the hole shelve downwards and inwards towards the lumen, and those sides, if the patient's recovery has been complete, show that the Haversian canals and lacunae have all been filled up by new bone, which gives the macroscopic appearance of a smooth and almost polished surface.

Large numbers of these skulls have been unearthed in France, and it is astonishing to find how few give evidence of unsuccessful operation, which goes to show how skilful those early operators became in their art to be able to avoid the many pitfalls such serious operations entail. Out of this large number, which represent many centuries of time and whose specimens are carefully preserved in both public and private museums in France, only two examples can in any way be referred to treatment for surgical affections. One of these was a skull taken from the Neolithic Cemetery of Bray-sur-Seine (Marne), and was described by Professor Parrot in the year 1881. Certain indications in connexion with the trephined area led the professor to infer that there had been an accumulation of pus in that region and the operation had been performed to set this free. It had probably been caused by a traumatic wound.[1] The other specimen, found by M. Gaillard in one of the dolmens of Port-Blanc at Saint-Pierre de Quiberon (Morbihan), was also described by Professor Parrot. An opening, 2½ in. by 2 in., showed a scraping on one side of the hole, but an abrupt edge on the other. This was considered to have been a wound at the first instance in which suppuration had taken place and trephining was performed to relieve pressure on the brain, due to pus.[2]

Both these cases, it will be seen, were caused at the outset by an injury, the wounds having become septic. The surgery involved, therefore, was for the relief of *pent-up pus*.

I think we may reasonably infer from the foregoing that these two cases were the exception and not the rule. The operation, then, *generally* performed was for ritualistic reasons, and the priest-doctor who officiated in such case would, by this experience, be the better enabled to deal with those *special* cases already cited. That is to say, the ritualistic operation came first, and later the attempted cure for morbid conditions of the bone.

We can therefore conclude that during the epoch known as the Carnac or final epoch of the Neolithic period a surgical procedure was instituted for the purpose of facilitating the exit of demons from the cranial cavity of man, and that this undertaking was the forerunner of cranial surgery for the treatment of fractures or morbid conditions of the skull itself.

It is strange to think that while in this and previous generations science has been the means of stimulating, beneficially correcting, and enlarging man's religious conceptions in a way never hitherto accomplished, the exact reverse was the case some four, five, or six thousand years ago. The real, intense, and intuitive religion of a race of men that inhabited nearly every country of Europe and were the builders of those massive, mysterious dolmens, those stately cromlechs, and those impressive open-air temples, with their processional avenues—these men regarded their religion of first and paramount importance, and compelled science to act as their servant and adapt itself to the special claims and requirements of their spiritual life. Which of these two forces will be predominant, say, five hundred years hence? Will it be Science or will it be Religion?

SATURDAY, NOVEMBER 30TH, 1929.

POLLUTION OF RIVERS.

Dr. H. McLean Wilson, the chief inspector of the West Riding Rivers Board, in his address to the Public Health Section at the Annual Meeting of the British Medical Association, printed at page 997 this week, makes the claim, which no one will question, that the state of the rivers under the jurisdiction of his Board is vastly different at the present time from their condition in the middle of last century, or even near its close, when the odours freed by the River Aire were noticed at Leeds Town Hall. Both this river and the Calder are now inoffensive and only slightly discoloured, while the Wharfe and the Nidd, more pellucid streams, are stocked with fish and lined with smiling villages, each with its own sewage purification works, and even small hamlets and separate farmhouses have made provision to prevent their sewage from entering the river water.

Dr. Wilson suggests that other local authorities should combine to take action after the manner of his Board. They have the power, he says, in the Rivers Pollution Prevention Acts, and yet they do not use it. This view receives support from a paper on river pollution read by Dr. J. B. Firth to the Public Works Road and Transport Congress held in London last week. "It seems to me," he said, "that some greater driving force is needed to compel the various authorities to shoulder their responsibilities . . . Nothing short of a bombshell appears to be necessary to move some of them." It might be advanced on behalf of authorities which have so far been laggard that the statute on which they are asked to rely is so framed that proceedings under it are hampered. It is not impossible that they may have felt reluctance to embark on processes which might lay them open to the rejoinder that their own sewage works contributed as substantially to any alleged pollution as the discharges they sought to repress. But whatever the grounds of their inaction may have been, it appears fairly certain that had local public opinion been strongly behind the local purification movement the councils, despite the limitations of the Rivers Pollution Prevention Acts and all other deterrents, would have been impelled to put their house in order, and, having done so, to initiate a campaign against the remaining offenders. In certain cases the necessary impulse may have been given by the existence of some clamant abuse, like the silting up of a river with ashes and slag, or by the contamination of its waters with sewage or trade refuse to such an extent as to make it a byword, and the good impulse, once given, has moved authorities to perfections of achievement quite beyond their original purpose. But when people are invited to support a scheme designed, not to dredge an encumbered river or abolish its malodorous foulness, but merely to improve the quality or prevent the deterioration of a stream which, judged by the casual eye, scarcely differs from normal, they are too apt to take the view that it is much ado about little, and so put the question by. The apparent clearness of a river is often a fallacious guide, for rivers possess a great power of oxidizing obvious impurities without at the same time being able to purge themselves with equal speed of the pathogenic bacteria committed to their waters by sewage effluents.

It is pleasant to note that amid the general indifference there exists one class of persons in this country who have striven consistently to prevent or arrest the degradation of better-class rivers, for the welfare of which they have done as much as or more than most public health authorities. The angling members of the community, through their various organizations, in seeking to make the rivers safe for fish, have at the same time rendered them fitter for the uses of man—the reception of sewage and trade waste excepted—than they would otherwise have been. The Salmon Fishery Act of 1861 empowered the prosecution of polluters of rivers who poisoned or otherwise killed salmon. The Salmon and Freshwater Fisheries Act of 1923 extends the protection to other fish besides salmon, makes it penal to injure them even short of death, and protects their spawn and their food. A river deoxygenated by sewage is hygienically objectionable; when it fails in consequence to support fish life the Fisheries Acts can deal with it. The public, however, cannot look to the angling interest to make or keep river water potable by man. "Fishes that tipple in the deep," provided the oxygen content is not too low, are greatly tolerant of admixtures of sewage, being immune to the bacteria which throng sewage effluents. The fact that a river is a good fishing river may say something for its amenity, but does not confer the cachet of safety; its waters may be charged with *B. typhosus*.

The standard which guides public health local authorities who interest themselves in rivers pollution prevention, though reached by a method different from that applied by anglers, is in its outcome of a somewhat similar character inasmuch as it is an amenity standard. It is founded upon the suggestion made by the Royal Commission on Sewage Disposal, which is not confirmed by any legal sanction, but generally accepted as a working rule, that sewage effluents discharged into a stream allowing adequate dilution should be such that a river, after receiving them, will not show obvious signs of pollution. Neither this standard nor the angling standard implies sterilization, for the Commission recognized that sewage effluents were liable to contain pathogenic bacteria, and took the view that their complete sterilization before discharge was impracticable at reasonable cost. The absence of signs of obvious pollution means that the river retains its natural appearance and presents the charm of fresh moving water to all who have eyes to see it. As the instance of London shows, it results also in the production of water of sufficient purity to be rendered potable after treatment. These are objects worthy of all endeavour.

The question of the state of rivers in this country increases in importance year by year, as the growing towns pour a swelling volume of sewage into the rivers, and as new industries generate fresh discharges which raise novel problems of treatment and disposal. Dr. McLean Wilson's opinion that special river boards are the best administrative machine for dealing with the questions arising is entirely commendable. The constitution of such boards respects the principle of local government, which, except in greatly restricted areas, has been prolific of good results. It is more in accordance with that principle than the single central department to control all rivers, vainly recommended by the Royal Commission on Sewage Disposal. To the attainment of the ends in view an informed and interested public opinion will greatly conduce.

THE MENTAL TREATMENT BILL.

THE Government's Mental Treatment Bill, introduced in the House of Lords by Earl Russell last week, is likely to arouse much interest in Parliament and in the country. The title alone—"An Act to amend the Lunacy Acts, 1890 to 1922, and such of the provisions of the Mental Deficiency Acts, 1913 to 1927, as relate to the constitution and organization of the work of the Board of Control, the exercise of the powers of the Board, and the protection of persons putting those Acts into operation"—indicates its important bearings on a matter of great public and professional concern, which closer examination of the terms and proposals of the bill amply confirms.

The chief amendments proposed are two in number. The first, which concerns the voluntary boarder system, is not new in principle, but extends the power already possessed by registered hospitals and licensed houses for private patients) to receive any person suffering from mental disorder who is desirous of voluntarily submitting himself to treatment. Under Clause 1 of the bill voluntary boarders may be received into public mental hospitals for rate-aided patients, and into any hospital or nursing home approved by the Board of Control, or, with the consent of the Board of Control, into single care. This amendment will bring the county and county borough mental hospitals into line in this respect with the City of London Mental Hospital at Stone, in Kent, and the Maudsley Hospital. The power to receive rate-aided patients into public mental hospitals has much to commend it, provided there are safeguards to ensure that no patient so admitted is kept indefinitely in hospital as a voluntary boarder if through mental deterioration he becomes incapable of volition. Legal provision to meet such a case is made in this bill for the first time: Clause 2 provides that a voluntary boarder who becomes incapable of volition shall not be retained thereafter on that footing for a longer period than one month. The second amendment of public importance relates to a matter which has always provoked controversy in the past, notwithstanding the obvious benefits that are likely to follow its adoption. This, we need scarcely say, is the provision for treatment of persons suffering from mental disorder, and for the time being incapable of volition, as "temporary patients" without certification for a period not exceeding six months. Under Clause 5 of the bill such temporary patients may in future be received into institutions provided by local authorities—that is, county and county borough mental hospitals—and into registered mental hospitals and such other institutions, hospitals, and nursing homes as may be approved by the Board of Control, or, with the approval of the Board of Control, into single care.

The general effect of these two proposals for amendment of the existing law will be to widen greatly the scope of the treatment of mental disorder, and facilitate its earlier application. The subject is of outstanding public importance, and we hope to return to it in more detail in a later issue, and also to discuss the other provisions of the bill which are of direct concern to members of the medical profession. Chief among these is the proposal in Clause 16 which gives effect to the recommendation of the Royal Commission on Lunacy and Mental Disorder that Section 330 of the principal Lunacy Act should be amended so as to provide that any person indicated therein shall not be liable to any civil or criminal proceedings unless that person "has acted in bad faith or without reasonable care." That is to say, in all such cases the onus of proof shall definitely rest on the plaintiff. Moreover, if any proceedings are taken, such proceedings shall be stayed on application to the High Court unless the court is satisfied that there is substantial ground for alleging bad faith or lack of reasonable care. This does not, indeed, give the full measure of protection generally claimed by the medical profession, but it is a substantial gain.

The bill will receive detailed scrutiny at the earliest possible moment by the British Medical Association's special committee, which has taken so large a part in advocating reform in the treatment of mental disorder and in demanding adequate protection for the doctor who has to discharge duties in pursuance of the Lunacy Acts.

BIOCHEMISTRY AND MEDICINE.

THE award of the Nobel Prize for medicine jointly to Sir Frederick Hopkins of Cambridge and Professor C. Eijkman of Utrecht, and for chemistry to Professor Arthur Harden and Professor H. von Euler of the Lister Institute and Stockholm, cannot but give the greatest satisfaction to the medical profession and to scientific workers in this country. Both of the English workers are biochemists, and both are notable as pioneer workers in various fields, which, once opened up by their efforts, have produced an increasingly rich crop of knowledge. It is notable that Harden, like Pasteur before him, chose yeast as the subject of his investigations. His experiments revealed a hitherto unsuspected phase in the process of alcoholic fermentation—namely, the formation of the intermediary hexose phosphoric esters. Following his lead, other workers demonstrated that these substances played an important part in the story of muscular activity, and it is now realized that phosphoric esters have a significance in animal metabolism which was undreamed of before Harden made his fundamental observations. Hopkins and Eijkman received the prize for their work on vitamins. Eijkman first described beri-beri as a clinical entity, and showed that it was in some way connected with a diet of polished rice. To Hopkins we owe the conception of "accessory food factors," and it was he who first demonstrated that these were definite physiologically necessary entities, quite distinct from all other known dietary substances. Characteristically, he was more interested in the discovery itself than in his personal claims as its author, and the facts found a place in his lectures for three or four years before the publication of his first paper on the subject. He used to say in these lectures that, while at hospital in the eighteen-nineties, he was profoundly impressed by the unsatisfactory state of knowledge about the essentials of nutrition, when only "protein" and "energy" were considered; and the profound effect of "quality" as distinct from "quantity" in diet was unrecognized alike by the physiologist and the clinician. This conviction suggested much of his later work. At first his views were not accepted, but scepticism was overwhelmed by the mass of confirmatory evidence, which has now grown into an extensive literature—so extensive, indeed, that Hopkins's earlier papers are in danger of being forgotten. It is fitting, therefore, that his work on vitamins should have been the occasion of the international recognition that he has just received. Sir Frederick Hopkins's biochemical interests have been, however, extraordinarily wide. With Sir Walter Fletcher he laid the foundations upon which has been built almost all the work on muscle physiology as we know it to-day. Early in his career he showed that the pigments of the wings of Pierid butterflies were composed of uric acid and its derivatives, and his method for the estimation of uric acid is still the most reliable at our

disposal. His excursions into the realm of protein chemistry resulted in the preparation of the first animal protein to be obtained in a chemically pure state. Next, led by his work on the Adamkiewicz reaction, he discovered tryptophane, and proceeded to demonstrate that its presence in the diet (and also that of a few other complex amino-acids) was essential to life; incidentally, in the course of this work he was among the first to make use of bacterial activity as a means of determining molecular constitution. He has been responsible for most valuable, though little-known, work on that curious substance Bence-Jones protein. His investigations into the mechanisms of biological oxidizations have done much to bring order into our knowledge of a subject of fundamental importance. Among other observations, his demonstration of the presence of xanthine oxidase in milk has made possible much of the accurate quantitative work on oxidases which has of late figured prominently in the output of the Cambridge school. Finally, he has isolated from tissues a new tripeptide, glutamyl-glycyl-cysteine, which undoubtedly plays an important part in the oxidization processes of living cells. There can be few physiologists or biochemists in this country who are not proud to acknowledge how much they owe to Hopkins's influence and teaching; and this feeling is certainly shared by all physicians who appreciate the great and increasing debt of clinical medicine to biochemistry.

LORD LISTER'S BIRTHPLACE.

PROBABLY none of the environs of London have changed more disastrously and more completely during the past sixty years than those about the borders of Middlesex and Essex. London has thrust out pseudopodia, carelessly, and engulfed now this bit of the countryside, now that, and what once were pleasant villages—Walthamstow, East Ham, West Ham, Forest Gate—are now well within the edge of Greater London, wildernesses of workmen's dwellings, overshadowed by the chimneys of great factories. Readers of Sir Rickman Godlee's *Lord Lister* will remember his description of Upton House, his uncle's birthplace, and the pleasant pictures of the house and its grounds that are reproduced in that charming book. This capacious old Queen Anne mansion, situated at Upton in Essex, was bought by Lord Lister's father in 1826, and in this pleasant country retreat Joseph Lister was born on April 5th, 1827. The estate on which Upton House stood has long been built over, and most of its gardens have disappeared; but the house itself was saved in 1885, when it was bought by the St. Albans diocesan authorities, and became the vicarage of the Church of St. Peter, Upton Cross. Now the house is once more in danger. The Bishop of Chelmsford, the Bishop of Barking, Lord Moynihan, and Sir James B. Slade, in a letter to the *Times* of November 22nd, point out that the vicarage is in need of extensive repairs, and that, even when these repairs have been effected, to keep it in proper condition would require a considerable yearly expenditure chargeable to the meagre stipend of the incumbent of the living. Indeed, in 1918 the diocesan authorities had contemplated selling the house, owing to its dilapidated condition, and no doubt would have done so but for the fact that the incumbent, the Rev. Allen James Parry, refused to give his consent, and carried out the necessary repairs at his own expense. Since then the vicar has paid considerable sums in preserving this fine old building, and at present the Ecclesiastical Dilapidations Measure levies an annual assessment on his stipend to meet the cost of future repairs and fire insurance. It is obviously unsatisfactory that the preservation of Upton House should depend on the generosity of the present and future vicars of St. Peter's Church, whose net stipend, we are reminded, is less than £400, and the Parochial Church Council appeals, therefore, for the sum of £1,800, to be capitalized by the Chelmsford Diocesan Board of Finance, and administered by them for the purpose of preserving Lord Lister's birthplace as the vicarage house of the benefices for generations to come. The signatories of the letter in the *Times* appeal to all who value the memory of Lister to subscribe towards the very moderate sum that is asked for, and they suggest that if the response is generous enough to bring in a larger amount the surplus would be used for setting up a memorial to Lister in the house itself. It would be a calamity if Upton House had to disappear, as did the Lister Ward of Glasgow Infirmary in the course of the reconstructions that were completed in 1924. The appeal has the support of Sir Humphry Rolleston, Sir William Lister, Sir StClair Thomson, and others. The present year has seen the acquisition, through the munificence of Mr. George Buckston Browne, of Charles Darwin's house at Down; the safeguarding of Lister's birthplace would be a becoming pendant to that gift to the public. Cheques should be drawn in favour of "Lord Lister's Birthplace Preservation Fund," and sent to the honorary treasurers of the fund at Upton House, Forest Gate, London, E.7, or they may be paid direct to the Forest Gate branch of the Westminster Bank.

ANIMAL BREEDING RESEARCH DEPARTMENT, EDINBURGH.

IT may be assumed that in the minds of those who were responsible for the creation of the Animal Breeding Research Department, now a constituent department of the University of Edinburgh, there were the notion and the hope that from its activities would emerge information that might be profitably incorporated into the practices of breeding animals of economic importance; it is unlikely that anyone at that time imagined that the interests of its staff would demand that by them man should be regarded as an appropriate experimental material and social biology as a necessary field of study. Yet this has happened. It was recognized quite early in the history of the department that the quickest and surest method of improving Soudanese sheep, for example, was to improve the Soudanese; that one could not understand sexuality and reproduction unless one studied these phenomena in a number of typical forms. One cannot argue from mice to men, but one can at least argue if one knows mouse, mule, monkey, and man. So it is that animal genetics includes human genetics and eugenics, and sex physiology the sexual life of man. This extension of interest has not been unprofitable, both intellectually and in the matter of endowment. There are many more people interested in the further control of the vital processes of man than there are in the further improvement of the sheep, and the activities of the Animal Breeding Research Department have attracted their attention. Mr. T. B. Macaulay, a prominent Canadian of Scots extraction, is the most recent benefactor of the department. He has endowed a lectureship and associated assistantships in order that the work on the endocrine aspects of senescence and of sex may be intensified. In making this gift to the University Court he states that he wishes to encourage those departmental activities which promise to add to our knowledge of the disabilities which at present stand in the way of human health and harmony. He holds the view that it is more important to add to man's knowledge of himself than to add to his knowledge of his commercial stock. The development of any research institution is conditioned by the opportunities it secures. It would seem that this department will inevitably approach nearer and nearer the medical school. Since this is to be desired, Mr. Macaulay is greatly to be thanked.

AN AMERICAN MEDICAL SCHOOL.

THE thirteenth instalment of the valuable publication *Methods and Problems of Medical Education*,[1] generously provided by the Rockefeller Foundation, differs from nearly all the previous issues in being entirely confined to the consideration of one teaching body—the Medical School of the Vanderbilt University at Nashville, Tennessee. This University was founded in 1873 by the munificence of Cornelius Vanderbilt of New York City, and the degree of Doctor of Medicine was first granted two years later. For more than forty years the medical school depended solely on students' fees, but in 1919 steps were taken to reorganize the medical school, and funds were forthcoming from the General Education Board and the Carnegie Corporation to construct a new medical school in which the clinical and laboratory departments would be closely correlated together and in the same building. The plans for this purpose were drawn up simultaneously with those for the University of Colorado at Denver, and were in the main adopted by the Medical School of the University of Rochester, New York, which was described in full detail in the seventh series of this publication two years ago. This new school at Nashville, with a new staff recruited from some of the best schools and laboratories in America and abroad, opened in 1925, and is arranged to accommodate a relatively small number of students, the classes being limited to fifty. The faculty was finally organized by a combination of new blood from outside and of the former clinicians, and staffing of the clinical departments, with the exception of obstetrics and gynaecology, has been arranged on a university basis, consisting of two groups—one whole-time workers in the school and hospital, and the other part-time clinical teachers. The beds in the hospital are allotted as follows: medicine 66, surgery 66, obstetrics and gynaecology 27, paediatrics 30, private patients 25, and coloured patients 36. Of the sixteen articles two are contributed by Professor G. Canby Robinson, who as dean gives the history and general description, from which the above details are taken, and as professor of medicine the account of that department; he, however, resigned both these appointments on July 1st, 1928. Neurology and psychiatry and dermatology are subdivisions of the department, as was paediatrics until last year, when it was separated and placed under the charge of Professor H. R. Casparis. In his account of the department of surgery Professor Barney Brooks pleads for more equipment in teachers, laboratories, and clinical material for his branch than for any other in the medical school, and considers that a university department of surgery should be potentially independent of all others, and should have 150 to 200 beds exclusive of the surgical specialties; he therefore regards the number of beds in his clinic as inadequate. The Vanderbilt University School of Nursing has been financially assisted by the Rockefeller Foundation, and provides two courses of study, one of twenty-eight months leading to the diploma of graduate nurse, and the other, with more academic teaching, leading to the degree of bachelor of science in nursing and the diploma of graduate nurse.

[1] *Methods and Problems of Medical Education* (Thirteenth Series). New York: The Rockefeller Foundation. 1929. (7½ × 11, pp. 130; illustrated.)

PREVENTION OF ACCIDENTS IN COTTON WEAVING FACTORIES.

FOLLOWING the precedent set by the spinning branch of the cotton industry, a committee consisting of employers and operatives in the weaving branch, together with representatives of the Factory Department, was constituted, at the end of 1926, for the purpose of revising and bringing up to date the safeguarding regulations agreed upon by a similar committee in 1912. The chairman of this committee, Mr. E. F. May, has now published a report[1] on the agreements arrived at. He sets out in full both the old and the new agreements, and explains the why and wherefore of the alterations. The new code will undoubtedly bring about considerable improvement in safeguarding and fencing, though possibly still greater improvement would have been effected but for the need, in a committee composed of persons with different interests, for bringing about a settlement by compromise. The carrying of warp beams and the lifting of heavy warp tension weights have been reasonably dealt with, though it might have been wise to retain the definite prohibition against women and young persons helping to lift beams into the looms. To minimize the risk of bursts, efficient safety valves are to be provided for and periodical inspections made of the steam drying cylinders of sizing (taping) machines. The clearance between shuttle and shuttle guard has been fixed at a half-inch maximum. Shuttle kissing was considered; the employers, however, having had no response to their offer, made in 1924, that they would substitute hand-threaded shuttles wherever practicable if weavers asked for and were willing to use them in the proper manner, did not now see their way to consent to the operatives' suggestion of unconditional abolition of the mouth-suction variety. Though none of the charges against shuttle kissing have been satisfactorily proved, the practice, like that of stamp licking, is a filthy one, and it seems a pity to leave matters as they are. In the cotton industry more than in any other is there a tendency for injuries following accidents to become septic, this sequel having been observed in 19.4 per cent. of cases, while no fewer than 65 per cent. of splinter wounds in weavers' hands become so infected. This committee therefore agreed to adopt the first-aid regulations that have already been approved by the cotton spinning committee, including the requirement that selected persons should be instructed in dealing with splinters. We again suggest that such instruction can most conveniently be given by the certifying surgeon. A joint standing committee has been appointed to meet twice each year for the purpose of reviewing the working of the agreements.

[1] Home Office Report on Conferences between Employers, Operatives, and Inspectors concerning Fencing of Machinery, First Aid, and other Safeguards in Cotton Weaving Factories. By Eliot F. May, H.M. Superintending Inspector of Factories. London: H.M. Stationery Office. 1929. 3d. net.

THE STUDY OF BOTANY.

THE devising of a thoroughly satisfactory scheme of medical education is unfortunately one of those insoluble problems that tend to be neglected, not because the present arrangements are tolerably satisfactory, but because there seems so little likelihood of any reform producing any great improvement. The receptivity of the individual student's mind is a fixed quantity, the amount of time that he can afford to spend on his education has already approached its limit; medical science, nevertheless, expands continuously, but it is impossible to put a quart into a pint pot. The favourite escape from this difficulty is to arrange for the student to learn "less and less about more and more." The pressure upon the student's time produced by the steady expansion of medical science does, however, induce a careful scrutiny into the subjects of his curriculum, and an inquiry into their real value. In particular the value of botany is often questioned, and it is interesting to note what Professor Boycott has to say in its defence in his introduction to the textbook of botany for students of medicine by Drs. Fritsch and Salisbury, of which the second edition has now appeared.[2] In the first

[2] *Botany: For Students of Medicine and Pharmacy.* By F. E. Fritsch, D.Sc., F.R.S., and E. J. Salisbury, D.Sc., F.R.S. London: G. Bell and Sons, Ltd. (10s. 6d. net.)

place, it is worth remarking that those interested in medical education might well look through this book simply to see the nature of a modern course of botany for medical students. Nearly the whole volume is occupied by plant physiology and biochemistry, and only one chapter is devoted to the classification of plants, while the characteristics of the familiar flowering plants are disposed of in nine pages. Modern botany is therefore quite a different subject from the botany taught to medical students thirty years ago. Professor Boycott, however, does not base his argument for botany on its utilitarian value to the medical student, but on the more general grounds expressed in the following sentences. "Medicine is a piece of applied biology and requires a generous training in the broad principles which summarize the relations of live things to one another and to inorganic nature. . . . The business of practical medicine is to make people feel better, and it does this by helping on the natural processes of repair and restoration, which are common to man and the earthworm: the mending of a broken leg depends on what the body does, the mending of a broken bicycle on what the engineer does. If anyone wants to play a good doctor's part in the running of this wonderful pageant, he ought to know biology, he wants to read his patients in the original. Besides, it makes medicine so much more amusing." Few will dispute the general principle that a doctor, whose work is entirely concerned with living tissues, must understand the broad principles of biology. The whole question is how these can be best taught to the medical student. The student with imagination and scientific insight will realize the relation between plant physiology and human physiology, but the practical question is whether an appreciable number of students ever realize that there is any connexion between the two subjects. The honours student is not the chief problem of education, because, if given a chance, he educates himself. It is in the case of the average student that the results of a good or of a bad education become apparent. We confess that we are doubtful whether the imagination of the average medical student can adequately bridge the gap between plant and animal physiology. It is, indeed, interesting to speculate how many teachers would agitate for the introduction of botany into the medical curriculum if it were not already there.

BRITISH INSTITUTE OF RADIOLOGY.

An exceptionally interesting programme of lectures, discussions, and demonstrations has been arranged in connexion with the annual meeting of the British Institute of Radiology, to be held on December 4th, 5th, and 6th at the Central Hall, Westminster. From 10 a.m. to 5 p.m. daily during the whole of the annual meeting, and continuing till December 21st, will also be held, at the premises of the Royal Photographic Society (35, Russell Square, W.C.1), an exhibition of radiography, illustrating the history, development, and scientific and industrial applications of *x* rays. Following the official opening of the meeting at the Central Hall, Westminster, by the Minister of Health, on Wednesday, December 4th, at 2.30 p.m., Professor Gösta Forssell will deliver the tenth Mackenzie Davidson Memorial Lecture, taking as his subject radiotherapy of malignant tumours in Sweden. On the same evening Dr. G. B. Batten will open a discussion at the Institute of Radiology (32, Welbeck Street, W.1) on the requirements of clinicians from radiologists and vice versa. At the morning session on December 5th Professor S. Russ, Mr. Geoffrey Keynes, Mr. Malcolm Donaldson, Dr. J. E. A. Lyndham, and Dr. N. S. Finzi will read papers on aspects of radiation therapy, and at the afternoon session this discussion will be continued, and Professor F. L. Hopwood and Miss F. E. Smallman will read papers on the use and abuse of radium needles. In the evening Professor A. S. Eddington, F.R.S., will deliver the twelfth Silvanus Thompson Memorial Lecture, his subject being *x* rays in the stars. During the *morning session on December 6th* the following papers will be read: Mr. W. E. Schall, on a single valve plant for diagnosis and deep therapy; Mr. Cuthbert Andrews, on a mobile *x*-ray unit; Dr. Ffrangcon Roberts, on modern radiological developments in Germany, with special reference to the new institute at Frankfurt; Dr. A. Oliansky, on output of transformers under different methods of high tension rectification; Mr. W. R. Gray, on a hot cathode tube with rotating anode; Dr. E. J. H. Roth, on the mekapion, an ionization apparatus for the absolute measurement of *x*-ray dose; and in the afternoon Miss S. F. Cox and Dr. F. G. Spear, of the Radiological Section of the Strangeways Research Laboratory, will read papers on tissue culture and its application to radiological problems; the action of *x* rays on living cells cultivated *in vitro;* and the immediate and delayed effects of radium on tissues cultivated *in vitro*. During the same session will be given demonstrations of cell division in living cells cultivated *in vitro*, of living cells under dark-ground illumination, and of stained specimens and charts illustrating the papers by Miss S. F. Cox and Dr. F. G. Spear. Members of the Institute are invited to bring friends to the exhibition and to any of the meetings, of which further particulars may be obtained from the secretary of the British Institute of Radiology, 32, Welbeck Street, London, W.1. On the evening of December 6th the Institute will hold its annual dinner at the Trocadero Restaurant, with the president, Mr. C. Thurstan Holland, in the chair.

SECOND INTERNATIONAL MALARIA CONGRESS.

In 1925 a committee of Italian malariologists, including Drs. Marchiafava, Ascoli, Bignami, Bastianelli, Dionisi, and Gosio, initiated and organized a "first international malaria congress," which was held in Rome in October of that year under the patronage of the Italian Government.[1] It was then resolved that in 1930, the fiftieth anniversary of Laveran's discovery of the malaria parasite, there should be a second international congress, and that it should take place at Algiers, where the discovery was made. Arrangements for this congress have now been completed under the authority and patronage of the French Government. It will be held at Algiers on May 19th, 20th, and 21st, with Professor Mesnil as president. The following subjects will be discussed: (1) The parasitology of malaria (including therapeutic malaria from the parasitological point of view); (2) anopheles mosquitos; (3) epidemiology and endemiology; (4) pathology; (5) quinine and other alkaloids and drugs in therapy; (6) prevention and control. Communications should be in English or French, and should be sent so as to arrive at the general secretariat of the congress (Pasteur Institute, Algiers) before December 31st. They will be printed and distributed to members before the opening of the congress. Members of the congress will include, in addition to representatives of Governments and institutions, all medical men, *biologists*, biochemists, and engineers who desire to participate. Applications for membership of the congress should be sent before January 15th, 1930, to the secretary general of the congress (Dr. L. Parrot, Pasteur Institute, Algiers, Algeria), accompanied by a postal order for 100 French francs. This subscription will entitle the member to take part in all meetings and official receptions of the congress, to receive a printed copy of the transactions, and to benefit by the reduction of fares allowed by the French railways and shipping companies. There will be optional excursions on May 22nd, 23rd, and 24th.

GEORGES CLEMENCEAU.

We are proud to recall that Georges Clemenceau, who died on November 24th at the age of 88, was a doctor of medicine, and came of a stock whose members for at least three generations had belonged to our profession. He began his medical studies at Nantes, and went to Paris in 1860, where, after holding a post as hospital intern, he graduated in 1865. He started practice at Montmartre, the district in which, at the age of 19, he had been imprisoned for shouting "Vive la République" in the street; but after a little while he went to America, where he remained for five years, resuming practice at Montmartre on his return. That Clemenceau's medical studies had some influence in determining his political philosophy is evident from the fact that he adopted his graduation thesis—in which man was described as a federation of anatomical elements, and the view was put forward that disease is not an entity distinct from the human body, but a change in physiological processes—as the foundation of his work *La mêlée sociale*, which appeared in 1894.

Sir George Newman's report for the year 1928 on the health of the school child was issued on November 25th, and, as in previous years, it consists of a summary of the work done by the local education authorities throughout England and Wales under the supervision of the Board of Education. The subject-matter is arranged under the following headings: the school medical service in 1928; physical education; the pre-school child; school dental work in the county area; malnutrition and school feeding; infective diseases and mortality in school children; and the mentally defective child; and, in a final chapter, Sir George Newman, as Chief Medical Officer of the Board of Education, surveys the relation between the problems of public health and those of education, and suggests possible lines of future development of the school medical service. We hope in a later issue to give detailed consideration to this report and to some of the important problems it raises.

The Semon Lecture for 1929 will be given by Dr. Harris P. Mosher, professor of laryngology, Harvard University, in the Barnes Hall at 1, Wimpole Street, W., on Thursday next, December 5th. The chair will be taken at 5 p.m. by Dr. Dan McKenzie, president of the Laryngological Section of the Royal Society of Medicine. The subject of the lecture is "The lower end of the oesophagus at birth and in the adult."

GENERAL MEDICAL COUNCIL.

ELECTION OF DIRECT REPRESENTATIVES.

THE ASSOCIATION'S CANDIDATES RETURNED.

The result of the election of two Direct Representatives for England and Wales has been that Dr. H. B. Brackenbury, LL.D., has been re-elected for five years from January 1st, 1930, having obtained 12,563 votes; and Mr. N. Bishop Harman, F.R.C.S., has been elected, to fill the vacancy caused by the death of Sir Jenner Verrall, with 11,943 votes. The unsuccessful candidate, Dr. A. G. Haydon, obtained 2,019 votes.

Registrar's Report.

The following report on the election, by the Registrar of the General Medical Council, was presented to the English Branch Council on November 26th.

The notices of the election were published on Friday, October 18th, and the last day for the receipt of nominations was Thursday, November 7th. Up to Monday, November 4th, only two nominations had been received, and it seemed probable that the election would be uncontested. A third nomination, however, came in on that day, and the arrangements for polling had to be concluded. Even if the election had been uncontested it would have been necessary to expend about £100 on printing and advertising and probably something like £50 on addressing, etc., because Section 8 (3) of the Medical Act, 1886, prescribes that the election must be completed within twenty-one days after the receipt of the Precept of the Returning Officer. If seven days are allowed for the return of voting papers and the requisite time for the counting of votes and other necessary work, it would be impossible to have the documents printed and issued within the remaining number of days. Consequently the expense of printing and a certain amount of addressing would have had to be incurred whether the election had been contested or not. Had, however, there been only two candidates for the two vacancies the Branch Council would have been saved an expense of about £250, principally in postage. The preparatory work is considerable, because it means obtaining an early proof of the *Register*, from which have to be struck out all the names of those not entitled to vote, and a number has to be inserted against each name to which a voting paper is to be sent. This forms the electoral roll, of which a copy has to be made, from which the entries are cut out and pasted on to the identification envelopes. The numbers on the outer covers, the identification envelopes, and the ballot papers have to correspond, and consequently the preparation of the issue of voting papers cannot be done hurriedly, and requires great care. It was, however, on the whole very well done, and but few mistakes arose. All of these were able to be corrected in time for the voters to take part in the election if they wished.

In accordance with previous custom the Directors-General of the Royal Navy, Army, and Air Force Medical Services were informed that any officers quartered at home could be supplied with voting papers on application, and twenty-six applications were received.

The week between the issue of the voting papers and their return is always very fully occupied in dealing with changes of address and clearing up incidental points which have arisen. Coming as it does this year in the week before the Council's session it means a considerable pressure upon the office staff.

Analysis of the Voting.

The total number of voting papers issued was 33,418, as compared with 32,758 issued in 1928, the constituency, therefore, having risen by 660 in the course of the year. Of this number, 422 were returned as dead letters—namely, 1.26 per cent. At the election last year there were 368 dead letters, and in the interval all these have been cleared up and, if new addresses were not obtained, voting papers were not issued. It is interesting to observe that, in spite of this care, the number of dead letters this year exceeds that of last year, which shows the extreme difficulty of keeping the *Register* correct so far as to provide an address which will find all registered practitioners.

The last date for the receipt of votes was Thursday, November 21st, and by the evening of that day all the envelopes had been sorted into numerical order, so as to prevent there being any duplicates, and on the following morning the opening was commenced at 10 o'clock. For purposes of record I may say that the opening occupied 16 clerks four hours, and the counting occupied 8 pairs two and a half hours.

The statistics of the election are given in the following table:

Number of papers issued	33,418
Less dead letters	422
Possible number of voters	32,996
Good voting papers received	13,839
Voting papers invalid:	
Identification envelope not fastened	110
Ditto unsigned	232
Ballot papers loose	60
Ballot papers incorrectly folded	8
Envelopes empty	42
Sundries (mutilations, etc.)	9
Too late	202
Number who took no part in the election	18,394

The percentage of the constituency which took part in the election was 43.70. The average percentage of those who have taken part in the nine elections of the present century has been 46.51.

The cost of this election was £12 9s. 6d. per 1,000 votes, or, if the postage is reduced to a penny for purposes of comparison with elections prior to 1919. £10 8s., as compared with £10 5s. 8d. last year and an average of £16 9s. 5d. per 1,000 over all the previous elections.

Norman C. King,
Registrar.

November 25th, 1929.

ROYAL SOCIETY OF MEDICINE.

The Prime Minister at the Annual Dinner.

The annual dinner of the Royal Society of Medicine took place at the May Fair Hotel on Thursday, November 21st. The Right Hon. Lord Dawson of Penn, president of the society, presided, and had on his right and left the principal guests in the Prime Minister (the Right Hon. J. Ramsay MacDonald) and His Excellency the French Ambassador. Others at the principal table included the Right Hon. Arthur Greenwood (Minister of Health), Viscount Lee of Fareham, the Right Hon. Hugh Macmillan, K.C., the President of the Royal Academy, and the Dean of Westminster. The Presidents of the Royal Colleges (Sir John Rose Bradford and Lord Moynihan of Leeds) were also present, and Professor A. H. Burgess (President), Dr. H. B. Brackenbury (Chairman of Council), the Editor of the *Journal*, and the Medical Secretary represented the British Medical Association. The total attendance was about 400.

In giving the loyal toast, Lord Dawson mentioned that on the same day last year there began that grave illness which nearly cost the King his life and the nation the loss of a beloved sovereign. This was a suitable gathering in which to state that the King in his recovery went *from* strength to strength.

The Prime Minister proposed the health of "The Royal Society of Medicine." In looking over its latest report, he said, he had been struck by the likeness of the doctor to the politician. The medical profession was less interested in the effecting of cures than in the maintenance of *health*; it was less interested in the particularized examination of one organ or part than in the harmonious and healthy interrelation of all. Medical science endeavoured to co-ordinate individual experiences into a scientific system, so that future practice might be based upon well-authenticated and tested experiment. In all these respects the profession followed the principles which had been most valid in the political sphere. Until a public man discovered the scientific principles that lay behind his projected legislation or administration he would remain a mere quack, wasting his time on patchwork. The Prime Minister then quoted and made some passing comments on the well-known passages in Ecclesiasticus praising the physician and describing the art of the apothecary. With regard to one passage, "Was not the water made sweet with wood that the virtue thereof might be known?" he said that that, of course, was in the nature of a reflection, but a reflection upon the old physician, not the modern one. Finally he gave the reminiscence, widely quoted in the press, of how he and the future Lord Dawson, being fellow students in London, had to tramp after midnight from Gower Street to Holloway because their combined resources, depleted by "a very respectable supper," were insufficient to afford a cab fare, and how they did not meet again until forty years later in Buckingham Palace. Could anyone, he asked, however gifted with divination, have said to those two students, "You will part to-night at Holloway, and not meet again until you are both invited to be the guests of His Majesty"?

Lord Dawson, in responding, described the Prime Minister as an apostle in the art of healing international strife. Speaking of the progress of medicine, he said that recent accessions of knowledge had belonged more to the domain of physiology and therapeutics than to the art and craft of surgery. With regard to radium, the past year brought a wider knowledge of its application and a better organization of the supplies. He touched also on what he called the "romance of the hormone"—"this little leaven which can, in its different forms, determine secretions and excretions, make or mar stature, alter character, change form and expression, and even be the arbiter of love and life." A passing reference was made to the success achieved by Laidlaw and Dunkin in the control of distemper in dogs. "This achievement is an admirable example of effective team work, and it is peculiarly fitting that the deliverance of the dog from suffering should have its origin in Great Britain. Here, as nowhere else, is the dog, with his fidelity, his never-failing response to every mood and feeling we possess, with even greater love for us than for his own kind, and his unalloyed friendliness, known and loved. It is charming to think that this benefit to the dog world should have come from laboratories in which a delightful confidence and camaraderie always exists between the workers and the dogs." Lord Dawson dealt finally with the application of medicine to the service of the community. The problem to-day, he said, was to bring medicine into closer understanding with the Government. "On one part of its territory the profession of medicine aims at close co-operation with administration so as to promote the health of the nation; on another part of its territory it concerns itself with knowledge, education, and research, and here it must be unfettered. Knowledge and the restless spirit which prompts its progress need a freedom and flexibility which cannot be found within the ringed fences of administrative departments. This, which is true of all professions, opens up a new problem of government. With the welfare of the people depending increasingly on specialized knowledge, would not the conjunction of skilled knowledge and informed administration in semi-autonomous bodies make, not only for vitality and efficiency, but for much-needed relief to overweighted government?" It was a plan which had already been tried in respect to electricity, broadcasting, and, more recently, radium.

Dr. A. P. Thomson, to whom was entrusted the toast of "The Guests," did them honour in some witty remarks regarding each, and in more serious vein spoke of the position of the voluntary hospitals. "It would be idle to pretend that certain tendencies have not filled us with uneasiness, even amounting to alarm. It has been said that the day is approaching when the State will control all the medical services in this country, and that the first great step to this end will be taken with the fall of the voluntary hospitals. The greatness of a country may be fairly estimated by the greatness of its institutions, and I confess that, to my mind, people who can talk glibly and cheerfully of the disappearance of great free institutions like the voluntary hospitals appear as reckless of the future of this country as they must be ignorant of its history and character."

Mr. Arthur Greenwood, Minister of Health, said at once that Dr. Thomson was utterly mistaken in his view that the Government had no regard for the voluntary hospital system in this country. From two points of view the voluntary hospital system was vital to the progress of public health. In the first place, it was interwoven with the growth of knowledge of problems affecting the life of the people, and in the second place, every hospital bed that existed in this country was needed. (*Mr. Greenwood's* remarks on this point were warmly applauded by the Prime Minister.) Mr. Greenwood went on to refer to the successful effort he had made to secure the help in an advisory capacity of the responsible heads of the profession, of whom Lord Dawson was one.* As he dug more deeply into the problems of public health he was appalled at the lack of knowledge and the amount of avoidable suffering. He welcomed without reservation every opportunity for the fullest co-operation with the medical profession; while he could not profess to understand their problems, he realized their difficulties. But he asked of the profession in turn that it should trust the Government, and believe that the Government was as much concerned with the problems as was the profession itself. "I hope that as this Government grows from strength to strength, or is succeeded by Governments of like purpose, the bond between your profession and the Government will grow also."

The Right Hon. Hugh Macmillan, K.C., who also responded to the toast, said that it had been his good fortune to be associated in public work with many members of the medical profession, and he had derived much benefit from such contacts. One of his pleasantest experiences was the reorganization of the method of compilation of

* See *British Medical Journal*, July 27th, 1929, p. 157. "Co-operation between the Medical Profession and the Minister of Health."

British Pharmacopœia. He found his amateur researches into the history of the standard catalogues of materia medica singularly interesting. He was surprised to find how comparatively modern was the scientific appreciation of drugs. The early London *Pharmacopœias* read like inventories of an alchemist's spells and potions. The appalling brews to which the unhappy patients of those days were subjected, compounded of millipedes, vipers, and skunks' stomachs and all manner of abominations, easily outdid the hell-broth of *Macbeth* witches. It was only within the last hundred years that medicine, like law, had finally emerged from the fogs of mediæval empiricism. Turning to the recommendations of the Royal Commission on Lunacy, over which he presided, Mr. Macmillan said that in the treatment of mental disorder the public had been excluded, by an antiquated system, from the benefit of preventive treatment. "Our great mental hospitals, so admirably equipped at the public expense, are prohibited from receiving for treatment any but certified lunatics. In other words, the disease must be completely established before the patient can obtain treatment." He was glad to think that within the last few years a measure had been introduced into Parliament which would throw open the State institutions to voluntary patients, and so enable preventive treatment to be directed to this most distressing and tragic of all ills.

RADIUM TREATMENT OF UTERINE CANCER.

REPORT OF THE MARIE CURIE CLINIC, LONDON.

THE Cancer Research Committee of the Marie Curie Clinic, formerly the Cancer Research Committee of the London Association of the Medical Women's Federation, has issued a report[1] on the radium treatment of cancer of the uterus carried out under its auspices during the period September, 1925, to March, 1929. The committee recognizes that as none of the patients has been treated more than three and a half years, deductions regarding permanent cures are not justifiable. On the other hand, the yearly revision of statistics is a useful guide to the evolution of radium therapy, and shows the value of this treatment in alleviating the condition of patients who do not survive to five years. In organizing the Marie Curie Clinic an attempt is being made to ensure conditions whereby carefully thought-out methods of treatment may be carried out and the results determined on a sufficiently large number of cases to prove their value. An organization differing somewhat from that common in British hospitals has therefore been considered necessary, and although patients admitted to the clinic will be under the entire charge of the individual members of the staff, the technique of treatment will be decided not by the individual surgeon, but by the staff as a whole, especially by the Cancer Research Committee.

The Changing Prognosis in Irradiated Cases.

The report opens with a classification of the results which have been obtained at different clinics in the treatment of cancer of the cervix by surgical operation and by radiology. In a monograph[2] on the history of the treatment of cancer of the uterus and its status in 1926 Dr. Janet Lane-Claypon concluded, from a survey of some 80,000 cases, that the final survival ratio was practically the same for patients subjected to irradiation as for those subjected to surgical operation. The changing prognosis in cases treated by irradiation is illustrated, however, in a report on the radiological treatment of cancer of the uterus presented by Dr. A. Lacassagne[3] to the Committee on Cancer of the League of Nations. At the Paris clinic, he states, the average percentage of five-year "cures" for the 350 cases treated from 1919 to 1923 inclusive was 20 per cent., for the 75 cases treated during 1923 it had risen to 30 per cent., and of the 33 operable or borderline cases treated, 16, or 48 per cent., were well after five years. The results have steadily improved since external irradiation has been combined with the local application of radium as a routine method of treatment, and by this method the field of usefulness of the radiological treatment of cancer of the uterus has been greatly extended. So far too few cases of cancer of the corpus have been treated radiologically to justify definite conclusions about the comparative value of radiotherapy and operative surgery, but Heyman showed in 1928 that "cures" after operation averaged 42.8 per cent., and after radiological treatment 33.2 per cent. The recovery rate at the Radiumhemmet averaged 43.3 per cent., and in operable cases it was as high as 60 per cent.

Methods and Principles of Treatment.

When the committee started work it decided to adopt the Stockholm technique, whereby intensive applications are given for short periods, the dose being interrupted by intervals of from one to three weeks, the total amount being given, however, within a period of not more than three to four weeks. By this technique the Radiumhemmet, during the period 1919 to 1922, obtained 24.2 per cent. five-year "cures," compared with 17.0 per cent. obtained by means of the Paris technique at the Fondation Curie during 1919 and 1920. Since that time the Paris results have steadily improved, and in 1923 the proportion of five-year cures (recorded in 1929) reached 30 per cent., while those from Stockholm have apparently been slightly less successful. The change is attributed to the fact that the Fondation Curie, while increasing the doses of the local treatment, has also been using as a routine supplementary irradiation with x rays or radium applied externally; at the Radiumhemmet supplementary irradiation has been used only for exceptional cases. A special advantage of the Stockholm method is that the last application is given at a time when the growth has undergone retrogression. At the end of the first week this process has only just begun, but after a fortnight shrinkage is marked, and at the last treatment the radium is nearer to the more outlying parts of the growth. On the other hand, the Stockholm method is not free from risk. It demands twice as much radium for the treatment of each case as the Paris method, and of all the patients treated by it 7 per cent. develop late radium reactions, a complication which does not occur in association with the Paris method.

At the Marie Curie Clinic in London modifications of the Stockholm technique have been adopted, with the idea of ensuring that the cone of effective radiation should be as wide as possible in the pelvic floor, and should coincide as closely as possible with the site of the growth. It was decided to spread the radium out between two or three flat applicators rather than to collect it together in one, or at the most two, containers. Putting all the radium into one vaginal applicator concentrates the radiation towards the centre of the cervix, instead of directing it as far out as possible towards the pelvic walls. In the majority of cases treatment aims at irradiating upwards towards the growth in the pelvic floor, and elsewhere, by a distance pack, screening off the radiation as far as possible. The Stockholm cylindrical applicators give a cylindrical zone of effective action, whereas the flat applicators give a zone shaped like a double cone, with the base corresponding to the plane of the flat surface. By means of flat applicators, therefore, radiation may be spread in the direction of the pelvic floor; with the same amount of radium in a cylinder the radiation would be more uniform on all sides, but not reach as far in the direction where it is most needed.

In treating cancer of the body of the uterus the workers at the Marie Curie Clinic have not been able to make use of previous experience to the same extent as they have in treating cancer of the cervix. In devising a method of distribution they have again attempted to arrange that the zone of effective action should coincide with the region involved, but in diagrams accompanying the report it is made clear that the method adopted gives too small a range at the fundus. The difficulty is to place radium tubes through a narrow cervical canal, with a proper regard for both site of growth and range of effect. Increased range is obtained by placing the flat applicators well up in each lateral fornix. The committee believes that it should be possible to enlarge these zones of lethal action by additional radiation from outside the body. So far the clinic has been hampered by lack of facilities for giving measured doses of penetrating x rays, but this defect will be remedied as soon as possible.

Technique of the Marie Curie Clinic.

The preparation of the patients about to undergo radium therapy includes a general examination, a blood count, and urine analysis; when necessary, a cystoscopic examination is made to determine the condition of the bladder. A bacteriological examination is important. Disinfection is carried out with acriflavine douches (1 in 1,000 normal saline) twice daily for a day or two before treatment, but in advanced cases with extensive necrosis more drastic measures of disinfection

are advisable. Patients with severe anaemia are kept in bed for two or three weeks for special treatment before the radium is applied.

A leucocytosis, even of moderate degree, is an indication for special care in the preliminary preparation. A leucopenia, or a lymphopenia with a normal number of leucocytes, suggests the need for cautious treatment; before irradiation measures should be taken to improve the general condition, a somewhat smaller first dose is given, and the blood condition is carefully considered before the dose is repeated. If the blood picture changes for the worse after the first irradiation the second application is delayed, and a slightly smaller dose then given. Slight lymphopenia is not infrequent in cancer cases, and is seldom, except temporarily, increased by the radium application.

Before applying the radium the bladder and rectum are completely emptied, and, during the treatment, if the bladder is not emptied naturally, a catheter is passed every eight hours. In most patients dilatation of the cervix can be done without difficulty, though in some, especially when the portio vaginalis has been replaced by a friable fungating mass, it may be difficult to find the upper cervical canal and uterine cavity. Only the gentlest manipulation should be used, on account of the risk of producing septic tracts in the broad ligaments or causing a perforation. If the canal cannot be found at the first treatment a vaginal applicator may be placed in the usual way, and at the second treatment it will probably be found possible to dilate the cervix and give the typical application. After the cervix has been dilated tissue is taken for microscopic examination, and the intrauterine applicator, containing the radium tubes in tandem, and equal in length to that of the uterine cavity, is then inserted. The intrauterine tubes contain a total of 50 mg. radium element, and their total screening is equivalent to 1 mm. platinum, with a secondary screen of rubber 1.5 mm. thick. The vaginal applicators (three in number) each contain 25 mg. radium element, and their total screening is equivalent to 1.3 mm. platinum, also with a cover of rubber 1.5 mm. thick. A firm gauze pack soaked in 1 in 2,000 acriflavine, and extending well up into the posterior fornix, serves not only to keep the applicators in position, but to protect the vaginal mucous membrane and keep the bladder and rectum as far away as possible from contact with the radium.

Three treatments are given, each of twenty-two hours, the second a week after the first, and the third two weeks after the second. The total dose averages about 7,000 m.c.h., and the maximum dose does not exceed 8,000 m.c.h. Patients of advanced age usually receive a smaller dose. In a considerable number of patients it is necessary to modify the dosage and method of application, increasing or diminishing the separate or total doses, or varying the time or time-spacing of the appl[illegible] conditions found.

T[illegible] have had only three applications of the [illegible] the growth has shown no response, as has occurred rarely, further treatment has been without effect. In such cases, if operation is possible, hysterectomy is advised Operable recurrences may also be treated by hysterectomy, but if they are inoperable a further local application may be followed by improvement. The committee stresses the importance of not repeating irradiation in cases of late radium reaction under the mistaken impression that there is a recurrence of growth.

Results of Treatment.

In presenting its statistics the committee has endeavoured from year to year to apply uniform principles. All patients applying for treatment between October, 1925, and April, 1929, are included in the general statistics, whether they were treated or not; but in the classified tables, which comprise only the cases treated up to October, 1928, nine have been deducted—four were lost sight of, in three there was a later hysterectomy, and in two the clinical diagnosis was not confirmed by the microscopic examination. The general results are as follows. Of 268 patients with cancer of the cervix, 182 were living in April, 1929; of 20 with cancer of the corpus there were 15 living, and of 12 with cancer of the vagina, vulva, and urethra 11 were living, representing, thus, a survival of 208 out of 300 patients. In the classified tables the cases of cancer of the cervix were grouped as early operable, borderline, inoperable, and hopeless; and those of the corpus as operable, clinically operable, and technically inoperable. From October, 1925, to October, 1926, 64 cases of cancer of the cervix were treated, the number in each of the four groups being 2, 10, 42, and 10. In October, 1928, the survivors of each of these groups numbered 2, 9, 21, and 1. Between October, 1926, and October, 1927, 47 cases were treated, the number in each of the four groups being 1, 5, 29, and 12, and the survivors in October, 1928, 1, 5, 15, and 2; and between October, 1927, and October, 1928, of 80 cases treated—this total comprising 6, 18, 36, and 20 in each of the four groups respectively—6, 17, 34, and 17 were living in October, 1928. In the above three periods the total survival rate up till October, 1928, was 50 per cent., 49 per cent., and 92 per cent.

The results of treatment in cases of cancer of the corpus uteri are as follows: 2 patients treated between October, 1925, and October, 1926, belonged to the first group, and were living in October, 1928; of 4 treated between October, 1926, and October, 1927, the numbers in each group were 1, 2, and 1, and the survivors in October, 1928, were 1, 2, and 0. Between October, 1927, and October, 1928, 4 patients were treated, 3 in the first group and 1 in the third; of these, all in the first group were alive in October, 1928, but the patient in the third group was dead.

France.

[FROM OUR OWN CORRESPONDENT.]

Slave or Fool?

VACATIONS are over, and our old school and hospitals resume their buzzing activities. But before the students were admitted the doors were open for the various annual congresses. For a few days we were made to believe that we had returned to the happy days of our youth. We did not realize the truth of Osler's words that in our life work we are either fools or slaves. The president of the Congress of Surgery, Professor Tixier, in the course of his address, insisted on the necessity for the surgeon of a systematic organization of his life. He declared that it was now an impossibility for an active man to have any time to spare for study or meditation, still less for recreation, rest, and family life. Professor Tixier seemed well aware of the great difficulty of effecting a radical change of habits in this country. It was a typical Frenchman who declared that he stood for progress but not for change.

National Insurance.

We still feel that we are heading towards a revolution in the medical world, thanks to the new social insurance law which the Government has promised to apply within the next few months. The profession at large is opposed to it, convinced that it is going against the good of the public. The Confederation of the Medical Syndicates, a new organization grouping 18,000 qualified men under the leadership of Professor Balthazar, is in open rebellion against the application of the law, though not against its spirit. A letter has just been addressed to Parliament in their name insisting on the main points that might, if conceded, make the law acceptable. For instance, the patient should be entitled to choose his doctor; professional secrecy should be guaranteed; the doctor should be free to treat and prescribe according to his own judgement. The mere enunciation of these conditions reveals the shortcomings of this most unpopular law. It goes against social ethics, as it offers too great a temptation for malingering and laziness; and we are very much afraid of its turning out a type of doctor such as the one who boasted of having examined and prescribed for seventy patients within sixty minutes.

L'Ordre des Médecins.

It has seemed necessary to the majority of the profession to create an "Ordre des Médecins," a medical council which may have to control the ethical application of social medicine. Up to now the doctor is perfectly free, and has only his own conscience to obey. We believe that our professional syndicates might be efficient if the power was given to them, but the administration favours a so-called independent organization under State control. The question is far from being settled. The important fact is that the profession is at last united and unanimous in all its recent decisions. Storms may serve a useful purpose.

Is the Radiologist a Public Danger?

The lay press has started a campaign against the "terrible danger" of x rays to the public, and especially to those who live in the immediate neighbourhood of the radiologist. The argument is purely theoretical, and no proof whatever has been offered. There is not one single case showing any injury done to anyone through distant and indirect exposure to the radiations. Also, in the present state of knowledge, the x-ray worker is too anxious

protect his own body to allow any harmful wave to escape from control. As Dr. Maingot ably replied, not only do we prevent the rays escaping from our rooms, but we prevent them escaping into our rooms, and the radiologist works within an *x*-ray-proof atmosphere. This information, immediately spread to the public through the press, has stopped the campaign and prevented a panic which might have proved most prejudicial to the specialist.

The Campaign against Noise.

Other waves are really harmful and more difficult to be dealt with—namely, sound waves—and the campaign against noise is attracting the attention of hygienists in many of our largest towns, especially in Paris. Professor Bordas of the Collège de France has made a careful analysis of the various noises in Paris, and distinguishes between the continuous rumble and the sporadic sounds. The former we easily get accustomed to, just as we do to the roar of the sea; as to the latter, we cannot but be the victims. For instance, in a district of Paris, during the construction of the underground railway, the engineers had chosen the small hours at night for exploding dynamite mines. Noise at night may compel the sleepers to keep their windows tightly closed, and in certain residential districts double windows are provided merely to obtain relative quietness. New street regulations are being enforced in Paris. First of all, silent zones are created in the immediate neighbourhood of hospitals. All horns must give the same low note. No horn is permitted to be used between 12 and 5 a.m. But, alas! this last rule, when infringed, raises a still more obnoxious noise—the nocturnal screech of the police whistle.

Euthanasia.

The country at large has been stirred by the trial of a young man of British descent who shot his mother and attempted suicide. In court he told a most pathetic story. It appears that the mother was so tortured by cancer that morphine gave no relief, and he determined to put an end to her sufferings at the risk of his own life. Before the jury there was no other defence than the pure statement of facts. Acquittal followed. It may be remembered that some time ago a similar case, in which the jury also gave a verdict of "Not guilty," was recorded in this column. All comment seems futile. Perhaps we should thank heaven that we do not have to serve on the jury in such cases.

Old-time Medical Practice in Edinburgh.

A LECTURE was delivered by Dr. Andrew Rutherford on November 13th at Edinburgh, under the Combe Trust, dealing with "Medical practice, past and present." The lecturer referred to the medical renaissance which took place in the reign of King James IV. towards the end of the fifteenth century. He interested himself in medical practice, and sufferers from toothache occasionally submitted to his ministrations at Holyrood, while on one occasion he operated on a woman for cataract, apparently unsuccessfully. In the year 1505 the town council granted to the barbers and surgeons of Edinburgh a Seal of Cause, confirmed by the King in the following year, under which they had the right to dissect the body of one criminal per year, and this was the first enactment of the kind in Britain. The surgeons of Edinburgh had also been given the sole right to make and sell aqua vitae within the burgh, a valuable privilege. In the same reign the magistrates made most stringent regulations, for controlling the spread of plague, and schools, booths, and markets were closed. An officer and assistants were appointed for supervision of town cleansing, and compulsory notification within twenty-four hours of all cases of plague was instituted—a very early example of notification of infectious disease. Later, in 1574, the town council instituted boiling in a cauldron as a method of cleansing foul goods. The lecturer, after dealing with the advances in medicine which followed Harvey's discovery of the circulation of the blood, mentioned many of the advances of the nineteenth century, dealing, for example, with the work of Bright, Simpson, Pasteur, Lister, Koch, Mackenzie, and Ross, and he concluded by saying that he was convinced that Edinburgh medicine in the years following the war was fully living up to the great examples and traditions of the past.

Civilization and Disease.

A lecture was delivered on November 20th at Edinburgh by Dr. Charles G. Lambie, under the Combe Trust. The lecturer dealt with the complex interaction which had taken place between man and his surroundings with the development of civilization. In early days human beings lived in small groups and led a vigorous life, while a great part of the body was exposed to sun and air. The chief dangers had arisen from conflict with animals, parasites, and precarious food supply, but epidemic diseases were probably uncommon. With the domestication of animals and development of agriculture food supply became more assured, but diseases like dysentery, typhoid fever, and typhus naturally sprang up. The spread of plague had been associated with the storage of grain and the prevalence of the domestic black rat. Malaria owed its disappearance from the country partly to the drainage resulting from high farming, and partly to the separation of cattle from human dwellings, which again had been consequent upon increased prosperity. Scurvy was common up to the middle of the seventeenth century owing to insufficient vegetable food and the consumption of salt meat during winter thereby entailed. The introduction of the turnip and other root crops from Holland in the seventeenth century, together with the use of the potato and the importation of fruit and vegetables, had almost eliminated this disease. In modern times the abundance of food had virtually abolished famine, but a new set of diseases had come into prominence in association with the excessive consumption of food, and especially of starch and sugar, combined with more sedentary habits of the people. Such diseases were diabetes, obesity, and some digestive troubles. Food had become too digestible, and it led to the recrudescence of deficiency diseases, such as scurvy, beri-beri, rickets, and dental caries, together with diminished resistance to infection. The industrial era, by transferring a large proportion of population from the country to the town, had promoted the spread of tuberculosis. It was the business of modern medical science to analyse the causes of disease and to devise means for their prevention.

Edinburgh Hospital for Incurables.

The annual meeting of the Royal Edinburgh Hospital for Incurables was held in Edinburgh on November 22nd. Mr. J. J. Herdman, chairman of the board, presided, and mentioned that the number of patients treated in the Longmore and Liberton Hospitals for the period to July 1st last was 375. The average daily number of patients under treatment during the year was 207. It was calculated that at least forty or fifty applicants in need of skilled nursing and constant medical care died before beds could be found for them, and many of the applicants who died had lived amidst surroundings where it was impossible for them to receive due attention. With the slow rate of admission which was possible in this hospital, the medical officers and managers had to exercise the greatest care in the selection of patients to see that they were in very real need, not only of attention, but of skilled nursing and constant medical care. It would be desirable to extend the hospital when possible, but as it had been necessary to take some £10,000 from the extraordinary income to meet deficiency on ordinary revenue, and as a similar inroad had been necessary for many years past, it was not possible meantime to engage in the large extension to Liberton Hospital which had been contemplated prior to the war. In those days the cost of a bed was approximately £45 per annum, as against the present approximate figure of £85. What was needed above all things at the present time was an increase in the annual income from subscriptions, and an increase of from £2,000 to £3,000 a year would place their accounts in a much more satisfactory position, and enable the work of extension from reserve funds to be proceeded with.

Inverness District Asylum.

The 65th annual report of the Inverness District Asylum has just been issued. The medical superintendent, Dr. T. C. Mackenzie, records that on May 15th, 1929, there were 736 persons on the register, of whom 16 were absent on probation, while the total number of cases under treatment during the previous year had been 882. The admissions during the year had numbered 153, or 18 more than the number for the preceding year. Of these 44 had previously been under asylum treatment, giving a readmission rate of 28.7 per cent. The ages of those admitted varied from 17 to 84, 10 patients having been admitted who were aged 70 and upwards. With regard to type of mental disorder, 25 had been cases of melancholia, 36 of mania, 38 of dementia, including 10 cases of dementia praecox, and there were 2 cases of general paralysis of the insane. As to cause, a hereditary predisposition to insanity was found to exist in 61 of the 153 cases, and in 60 of the cases there had been at least one previous attack of mental disorder. Senility and alcohol were among the assigned causes in 21 and 4 cases respectively. Of the 67 patients discharged, 39 were recovered, giving a recovery rate calculated on the admissions during the year of 25.4 per cent. for both sexes. Twenty-eight cases were discharged unrecovered, either by transfer to other institutions, or to the care of relatives, or to be boarded out with suitable guardians in private dwellings. The number of deaths during the year had been 79, of which 24 were due to pulmonary phthisis and 23 to senile decay.

England and Wales.

Water Supply and the Public Health.

A Public Works Congress and Exhibition was held at the Agricultural Hall, London, last week, when, under the auspices of various associations of local authorities, a very large display of plant and materials for highway construction, sewage disposal, and water and lighting supplies was assembled. Although there was no public health section this year—such a section is arranged for alternate years—a certain part of the proceedings of the congress had an interest from that point of view. The British Waterworks Association arranged a special conference at which a report, just published, of an advisory committee on water, appointed by the Ministry of Health, was considered. It was rather surprising to gather from the discussion that in some parts of the country "domestic supply" does not include the supply to water closets and household baths, for which a special charge is made. The fact is that when the early Water Acts were passed these conveniences were exceptional; now they are universal, and special charges for them no longer accord with modern conditions. Again, in some cases supply pipes under highways from the main to private premises are the property of and maintained by the private owner. The Ministry of Health Committee proposes—and the water authorities appeared to agree—that the provision and maintenance of all these supply pipes should be regarded, like the mains and other works, as part of the normal operating costs of the undertaking.

Among several interesting contributions made to the conference on the scientific side was one by Mr. J. B. Firth, D.Sc., of University College, Nottingham, on the preservation of rivers and streams from the standpoint of water supply. One point was that periods of warm weather associated with intensive sunshine are of considerable value in the purification of rivers. There occurs, during spells of fine weather, a marked increase in the oxygen content of a river, which can only be attributed to the equally marked increase in the carbon dioxide content, accompanied by intensified photosynthesis. Intensified photosynthesis increases the oxygen content of the river; this in turn, together with an increase in temperature of the water, increases the rate of oxidization of organic matter in the river, whereby the carbon dioxide content is further increased, and so the process goes on. The condition grows more and more favourable for the oxidization of organic matter as the oxygen content is increased. During these intensive periods of oxidization it follows as a natural result that there is a thorough cleansing of the rivers, save in the case of waters which are highly charged with bicarbonates.

The purity of drinking waters from the biological aspect was discussed by Mr. W. Rushton, D.Sc., biologist to St. Thomas's Hospital Medical School. Possibly it was news to some of his audience that there is a seasonal sequence in the types of organism appearing in drinking water. The spring is the period of the diatoms; late spring and early summer, the green algae (unicellular and filamentous); in later summer the blue-green forms are most prevalent, overlapped by the protozoa, which are followed in turn by the second flush of diatoms. Certain forms appear to give trouble one year, and different forms another year: also those which give rise to odours and tastes in one area may not do so in another, so that it is impossible to lay down hard-and-fast rules for dealing with them. Certain reservoirs, as the various reports of the Metropolitan Water Board show, are more prone to living contents than others. It is difficult to say why certain organisms, apart from bacteria, multiply rapidly in one year and not in the year following. It is known that light is a factor, but as to the chemical determinants, said Mr. Rushton, there is a singular deficiency of knowledge. He emphasized the need for continuous study of the streams which supply the principal sources of drinking water; continuous biological examination of the life contents of waters after impounding, to determine what increase or decrease in numbers had taken place; and further experiments to determine how best to combat the life contents of a water supply, either by mechanical or other means, before trouble arose. Many anglers raise the question of using more artificial reservoirs for fishing purposes, but apart from the possible dangers of the introduction of organic matter in the waters, said Mr. Rushton, experience showed that impounded waters were not the best areas for fish, owing to lack of food, too great depth, and lack of vegetation in the feeders of the reservoir.

Reconstruction of Leicester Royal Infirmary.

Reconstructed buildings forming part of the Leicester Royal Infirmary were opened by the Duchess of Rutland on November 13th. The converted portion is the central wing, containing three wards, which is to be named the Sir Edward Wood Wing, in memory of a former chairman of the board, who was responsible for much of the recent progress of the hospital. Each of the three wards contains thirty beds, together with two single-bed annexes for serious cases. Two new operating theatres have also been provided, as well as dining rooms and kitchens equipped with labour-saving appliances for the assistance and comfort of the staff. The total cost of the new provision is £87,000, of which a balance of only £3,500 remains to be raised. The policy of reconstruction was decided on before the war, but was delayed for various reasons, chiefly financial, and ultimately the work was put in hand as the result of a gift of approximately £18,500 by Mr. H. T. Mills, who desired that a third ward, in addition to the two originally intended, should be erected to the memory of his father. At the opening ceremony a religious service was conducted by the Bishop of Leicester and ministers of other churches, which followed exactly the order of that used at the opening of the old ward sixty-seven years ago. Mr. J. G. Pickard, J.P., the present chairman of the board, gave some account of the recent developments of the hospital. In 1914, when the present reconstruction was first proposed, the in-patients numbered 4,000, and by last year the number had risen to 7,380. He added that the board felt that the new building was now worthy of Leicester and in the front rank of the voluntary hospitals of this country. The Duchess of Rutland, in a graceful opening speech, remarked on the fact that a small provincial hospital had grown to such magnitude in thirty years as the result of voluntary contributions. The annual expenditure had increased with the growth of the hospital, but the generosity of the subscribers had kept

pace, and she knew what a great asset this modernized institution would be to the city and county of Leicester. A vote of thanks to the Duchess was proposed by Dr. Astley V. Clarke, senior physician, and seconded by Mr. Cecil Marriott, senior surgeon. The deputy lord mayor handed over a cheque for £651 as a gift to the infirmary from the workmen's clubs of the city; it may be remembered that on May 11th (p. 877) we gave some details of the systematic and generous supply of funds which is being obtained by this institution from such sources.

Royal Dental Hospital, London.

The Royal Dental Hospital in Leicester Square opened its doors on November 3rd to more than three hundred visitors, when the various departments of the hospital were made available for inspection. In the conservation room clinical cases were shown, as well as bacteriological slides and specimens, models illustrating abnormalities of the teeth, and other devices showing various stages in the construction and adaptation of porcelain jacket crowns. In the appliances room prosthetic cases were on view, and there was an exhibition of skiagrams in the *x*-ray room and of photomicrographs in the research department. The whole exhibit, including a department of electro-therapeutics, the first of its kind in association with a dental hospital in the British Isles, revealed how many-sided modern dentistry and dental teaching have become. In the evening of the same day past and present students of the dental school dined together at the Trocadero under the chairmanship of Mr. W. J. May. Proposing the toast of "Success to the Hospital and School," Mr. May mentioned that the institution had now been established for seventy years, and for nearly thirty years in its present building. In many respects, such as dental radiography, it had played a pioneer part in dentistry. The reputation of this school, like that of any other, was largely embodied in and increased by the reputation of the men and women it had sent out into practice, and Leicester Square might indeed be proud of its children. Responses to the toast were made by Mr. E. D. D. Davies, on behalf of past students, and by Mr. F. F. V. Manfield, on behalf of present students; the latter referred to the revival of the students' society during the past year—a matter of considerable value to the students, since it accustomed them to address their fellows. The Dean (Mr. H. Stobie), commenting on the activities of the school, mentioned that there had been no marked influx of students, a fact not peculiar to the Royal Dental Hospital. Moreover, on comparing present-day with pre-war figures, allowance had to be made for the fact that there were now very flourishing provincial schools, which attracted the students from their own districts. In examinations the school showed a very successful record; the passes averaged 70 per cent. As regards research, the hospital had an excellently equipped laboratory; some work of a most striking character had already been completed under the superintendence of the advisory committee and Dr. Fish, which had been officially recognized by the Medical Research Council. The hospital had also been to the fore in organizing post-graduate study; many graduates had come from the provinces to take courses lasting three months or longer. In orthodonture the teaching was not restricted to any one school of practice; all methods were taught. One disability hitherto had been that the hospital had no beds; this had been made good by an arrangement with Charing Cross Hospital, only a few hundred yards away, whereby a certain number of beds would become available, it was hoped, at the beginning of next year. The Dean also mentioned certain new appointments to the staff, and certain resignations, the latter including that of Dr. Harvey Hilliard, who for thirty-three years had been honorary anaesthetist. Mr. S. A. Riddett proposed the health of "The Guests," who included Sir William Goschen, the chairman of the hospital, and a response was made by Mr. Malcolm Knott, president of the British Dental Association. Mr. Knott referred to the need of keeping up the supply of dentists; while he welcomed additional degrees and diplomas, he urged that the portal of entrance should be kept sufficiently wide to maintain the ranks. It was asking too much of a man to spend six or seven years in courses of study before he could begin practice. Mr. Knott also pleaded that all dentists on qualification should join the British Dental Association, if only out of gratitude for what that body had already done for the profession. The toast of "The Chairman" was proposed by Mr. A. T. Pitts.

The London Clinic and Nursing Home.

The foundation stone of a large new nursing home for London, which is to be constructed on more comprehensive lines than any existing institution in the metropolis, and is described as "not a hospital, but a hotel for sick people," was laid by the Duchess of Atholl on November 27th. This building, which will face Marylebone Road, Harley Street, and Devonshire Place, at the north of the "consultants' quarter," is the result of co-operation between specialists in different branches of practice for the purpose of providing more elaborate equipment for the investigation and treatment of disease than can be afforded by individuals working alone. The members of the medical group participating in the venture number at present twenty-three well-known London consultants. As may be imagined, the business side of the undertaking has occasioned some perplexity. The members of the group began to discuss a co-operative scheme ten years ago, and negotiations were opened with some persons of financial standing, but it appeared that nothing could be done unless the members of the group themselves were prepared to take some financial risk, which would be contrary to medical ethics, and so the negotiations came to an end. Later, however, a number of business men were found who, grasping the importance of the objects aimed at, and the difficulty of the professional position, took the financial responsibility, asking only in return that the members of the group should take a long lease of a block of thirty-six consulting rooms in an adjoining building. This is the only monetary transaction in which the members of the group have been concerned, but they are to form among themselves a committee to advise, in an honorary capacity, those responsible for the business side of the undertaking. The clinic is a limited company (the London Clinic and Nursing Home, Limited), the shares in which are held by between two and three hundred individuals, but on this side of the venture the medical men concerned have no interest. From the speech of Dr. Moreland McCrea, chairman of the group, at a luncheon which followed the stone-laying, it appears that the building will consist of 200 bedrooms, together with laboratories, *x*-ray department, and other provisions like those of the modern hospital, the equipment incorporating various suggestions made by the group after visits to Continental clinics. The accommodation for patients will range from single rooms to suites, in which a relative could remain with the patient; and it is hoped to provide a number of beds at a relatively low inclusive charge for those whose incomes are just above the limit which would entitle them to hospital benefit. It is proposed to have a staff of over one hundred nurses, for whom a hostel in the suburbs is to be built, so that a special nurse can be detached for a particular case. There will also be two resident medical officers for emergencies, but they will in no way usurp the authority of the patient's own medical man. It is an essential part of the conception that the patient should remain in contact with his regular adviser. The nursing home will be open to the patients of any medical man, though the members of the group will have the first call upon empty beds; and any surgeon to a hospital of recognized standing may operate in the theatres of the new building. Mr. Allan Hepworth, who is to be the managing director of the clinic, added some further information from the business side. He emphasized the point that the new building would not be a hospital, nor be administered on hospital lines, nor would it compete with hospitals. It would be directed more on the lines of a hotel, especially as regards the freedom and facilities of patients. Much attention would be paid to proper cooking and dietetics, and the help of certain women skilled in household and domestic science had already been secured. The scale of charges he mentioned ranged, for people of moderate means, from eight to ten guineas a week inclusive, and, for well-to-do patients, from twelve to thirty or thirty-five guineas a week.

The Causes of Cancer.

In a Chadwick public lecture, delivered on November 22nd, Professor A. E. Boycott said that, although the cause or causes of cancer were still under investigation, enough was now known of the conditions which led up to the disease to justify action designed to diminish its incidence. It was clear that cancer was practically confined to middle-aged and elderly persons, but there was no evidence that it was infectious in the ordinary sense, or that a tendency to it was commonly inherited. It occurred more frequently in urban than in rural districts, and its appearance was often preceded by chronic irritation and injury. The careful investigations of Mr. C. E. Green, a legal publisher in Edinburgh, had led him to associate the high cancer death rate in Scotland and France with the use of coal as fuel, and Dr. Scott's inquiries had brought to light very clearly the connexion between superficial injuries incurred in the shale-oil industry and the subsequent appearance of cancer. Certain mineral oils used for lubricating machinery had now been recognized as a cause of mule-spinners' cancer in Lancashire. There were grounds, therefore, for suspecting the products of burnt coal, and substances connected with mineral oils whose origin might be supposed to be related to coal. This suspicion had been much strengthened by Yamagiwa and Ichikawa's discovery that the repeated application of tar to animals caused cancer; tar preparations had proved most effective when they were applied to the skin of mice, though cancer hardly ever appeared in less than three months from the beginning of the irritation, and it was generally necessary to continue the application for six months. As the natural span of life in the mouse was rather less than three years, it followed that such a period as six months corresponded with fifteen years in the life of man. The time interval in mice and human beings was therefore comparable, since it was only after many years' exposure that cancer appeared in shale-oil workers and mule-spinners. In mice it had further been shown that the irritation need not be continuous; a few applications of active tar might lead to the appearance of a tumour several months later. Hence, in searching for the cause of any case of cancer the events of fifteen or twenty years previously must be considered, as well as the immediately preceding history. As a matter of practical hygiene, concluded Professor Boycott, irritation in all forms was to be avoided, and the case against the products of burnt coal was so strong that the smoke nuisance should be stopped.

Correspondence.

THE BEGINNING OF THYROID THERAPY.

SIR,—The case of myxoedema recorded by Dr. Arthur Hawkyard (*British Medical Journal*, November 16th, p. 932), in which complete recovery followed a course of injections of thyroid extract in 1893, is remarkable in that there was no recurrence of the symptoms after the treatment had ceased up to the time of her death last month, at the age of 87. This course of events suggests either that the myxoedema was due to a temporary disablement of the thyroid gland which subsequently recovered and carried on its function after the thyroid extract was discontinued, or that an accessory gland hypertrophied sufficiently to compensate for the atrophy of the thyroid gland itself and to maintain good health for thirty-five years. Three cases of spontaneous recovery from myxoedema have been recorded by Hun and Prudden, by Mrs. Garrett Anderson, and by Fraser of Paisley. In the third case no recurrence had taken place ten years after recovery. A similar explanation would account for the recovery in these cases. The result of the treatment of my first case of myxoedema by thyroid extract was not first published in 1893, but two years earlier, in a paper read at Bournemouth, at the Annual Meeting of the British Medical Association, which appeared in the *British Medical Journal* of October 10th, 1891 (p. 786). This patient, under the influence of continued thyroid treatment, remained in good health for twenty-eight years, and died in 1919, at the age of 74, from cardiac failure.—I am, etc.,

Manchester, Nov. 19th. GEORGE R. MURRAY.

HYDATID DISEASE IN ICELAND.

SIR,—With reference to the interesting article on hydatid disease and public health in the *Journal* of November 23rd (p. 970), and the measures advocated by Sir Louis E. Barnett to diminish its ravages in New Zealand, it may be of interest to record what has of late years taken place in Iceland, from which country I have recently returned.

In Iceland it is well known that until recently hydatid disease was of very common occurrence. Fifteen years ago, however, the matter was taken in hand. It was forbidden to keep any dogs within the boundaries of Reykjavik, the capital city, which itself contains nearly 25,000 inhabitants—almost a quarter of the total population of the island. An educational campaign was also conducted throughout the country, explaining how the disease was produced and how it might be avoided. Especial reference was made to the necessity of preventing house-dogs from soiling the food utensils, and especially the "skyr bowls," from which the national dish, "skyr," dating from early Viking days, was eaten, and which, being placed on the floor when empty, were often licked clean by the dogs.

As a result of these measures the incidence of the disease has greatly diminished, and for the past six years the yearly number of fresh cases has fallen to a figure varying from 27 to 50[1] throughout the whole island.—I am, etc.,

PERCIVAL HORTON-SMITH HARTLEY.

London, W.1, Nov. 21th.

LOCAL NICKEL POISONING WITH BISMUTH INJECTIONS.

SIR,—The following two cases appear to show the possibility of local poisoning by nickel if a syringe with a nickel-plated piston is used for bismuth injections.

1. I was injecting a man with his third dose of vaccine by means of a syringe which I had last used (four days previously) for thiobismol—a water-soluble bismuth preparation. The syringe had been repeatedly "coughed" empty, but not washed out. I noticed that the vaccine became slightly green in the barrel, but as the syringe was kept in spirit, and as I knew the trace of bismuth was aseptic and harmless, I did not reject the vaccine. That the green colour indicated substitution of bismuth by nickel did not occur to me then. Within five minutes of the injection pain started in the arm, spreading to the shoulder and lasting for three weeks; it was severe for five days. The arm was red and swollen, and a lump as large as an egg appeared and took three weeks to subside. There was no fever.

2. In the same week I injected another patient with morphine solution the day after using the same syringe for thiobismol. Again the solution was tinged with green, and no more morphine was available. Promptly the forearm became red, painful, and swollen, but the reaction was neither severe nor lasting, and there was no fever.

In both cases the symptoms were too rapid and afebrile to be caused by sepsis or vaccine. The greenish colour indicates nickel as the irritant, rather than copper from the piston. I have had no trouble or pain with thiobismol since reserving an all-glass syringe for its use.

I wrote to the makers (Parke, Davis and Co.) of the excellent thiobismol. They replied that this was the first occasion on which local poisoning from thiobismol left in contact with a metal plunger had been brought to their notice, and they agreed that an all-glass syringe should be used for all compounds of the heavy metals. Logically, they added, the needle also should be of platinum-iridium instead of nickel-plated or chrome steel.

There is perhaps a natural disinclination to wash out a syringe of which the contents have always been aseptic, because water might not remain sterile, and spirit is an irritant to the tissues and precipitates some solutions.

If there is pain after a bismuth injection the bismuth is naturally blamed; hence the nickel poisoning would escape detection. This may account for some of the divergent opinions as to the pain produced by injections of the various bismuth preparations. Dr. Svend Lomholt, in his full and valuable paper on bismuth injections in the *Journal* of November 16th (p. 887), makes no mention of this possible toxic complication. Evidently it has been too little recognized—possibly not at all, for new knowledge derived from error commonly remains unpublished.—I am, etc.,

REVOCABLE STERILIZATION OF THE FEMALE.

SIR,—Most of the operative procedures designed to render the female sterile suffer from the disadvantage that their effects are permanent. In many cases, however, only temporary sterilization is required, and I would suggest that this might be achieved by a simple yet thoroughly effective operation, which was first described and successfully performed by Professor Forel of Zürich and Lausanne His method is to make a small opening in the abdomen, dislocate the fimbriated ends of the Fallopian tubes, and tie them out of the way. By means of a single catgut stitch they can be kept permanently away from the ovaries so that the ova drop harmlessly into the peritoneal cavity.

The great value of this operation lies in the fact that the process can be reversed, and the ends of the tubes restored to their original position, so that the woman becomes once more capable of bearing children. Moreover, as the ovaries are untouched, the natural secretions are carried on, and none of the disastrous consequences which often follow removal of the ovaries can occur. Dr. Forel assured me that if this operation is performed under strict antiseptic conditions it is entirely without danger or even inconvenience to the patient later on.—I am, etc.,

G. LINDSAY JOHNSON, M.D.,
F.R.C.S.Eng.

Durban, Oct 18th.

TREATMENT OF SCALDS AND SUPERFICIAL BURNS.

SIR,—The problem of treating scalds and burns is obviously twofold: to lessen shock and to avoid sepsis. It is well to remember that shock is not completely accounted for by the first contact with the exciting cause, but is aggravated and maintained by excessive stimuli from the damaged skin surface upon the central nervous system.

In the treatment of shock, more especially in children, I regard sleep as a factor of paramount importance. Potassium bromide has many advantages as a sedative and few disadvantages. Doses of 2 to 5 grains, according to the age of the child, and given every three or four hours, generally induce sleep. In the treatment of adults an injection of morphine (1/6 grain) may be more effective. When the injuries are severe brandy and salines may be administered with advantage every three or four hours, and these measures, varied according to the needs of the case, may be regarded as a routine treatment for combating shock.

While investigating local applications for the avoidance of shock from the continued pain of scalds and burns, I reached the conclusion that an ointment would give greater and more immediate relief than any other application, and that the pain caused by changing dressings would be reduced to a minimum. Observing that the injured parts often look too moist and sodden to heal readily, I decided that a suitable ointment should contain a drying substance. Calamine readily presented itself to the mind, and experiment proved that burns and scalds in contact with this substance were kept practically dry. Further experiment showed that calamine by itself was not sufficiently soothing, and the need for a bland and healing substance led to the addition of zinc oxide to the ointment.

To deal with the second part of the problem—namely, that of sepsis—the ointment obviously required the addition of an antiseptic. For this purpose an antiseptic oil suggested itself, and three were tried—carbolic, eucalyptus, and terebene. Of these, oil of terebene was found to be the best. Ordinary yellow vaseline was adopted as a basis because it is an easy and smooth-spreading material, and in conjunction with the other substances produces an ointment which makes up well and keeps indefinitely. After trying various proportions of these ingredients the following formula was found to be the most suitable: Calamine 30 grains, zinc oxide 30 grains, oil of terebene 15 minims, yellow vaseline to 1 oz.

I have treated every case of superficial burns and all cases of scalds which have occurred in my practice for the last seven years with this ointment, and have never been disappointed with the result. One or two other medical men have tried it with similar good results, and it is remarkable in minor cases, and even in the more severe cases, how quickly the injuries heal. I attribute this, in great part, to the drying effect of the calamine, because excess of moisture not only prevents rapid healing, but also, I am sure, renders the injured surface a much better culture ground for septic organisms.

I use the ointment evenly spread on white surgical lint and, of course, apply it as quickly as possible after the injuries are received. I snip blisters immediately, or on the following day, and to facilitate the removal of dead skin or slough sometimes immerse the affected part for a short time in a warm soda bath.

The last case treated in this way is at present convalescent in the Buxton and District Hospital, and I append a short history.

J. J., aged 11 months, was seen by me on the evening of November 2nd; he was severely scalded by boiling water all over both legs as high up as the middle of the thigh. The feet were partially involved. One single blister on the right leg extended from the outer side of the ankle to well above the knee. In addition, both hands and wrists were scalded. I immediately applied the ointment, and he was then admitted to hospital. On admission he was found to be suffering severely from shock, and was put on three-hourly salines and given a little brandy. In addition, he had a three-hourly mixture containing a 2-grain dose of potassium bromide. Later in the evening his injuries were again dressed with the ointment. During the night he was very restless. On the following morning he was somewhat better, and shock was less marked. Dressings were carried out twice daily. On the second night after admission he slept fairly well. The wounds healed rapidly, and in a week the child was out of danger. On November 14th, with the exception of a small area at the right ankle, which was clean, his wounds were completely healed.

—I am, etc.,

J. A. HENDRY, M.B., Ch.B.,
Honorary Physician, Devonshire Hospital, Buxton.

November 18th.

RELIEF OF PAIN IN LABOUR.

SIR,—The correspondence in your columns on this subject touches a matter of interest to all who practise obstetrics. Perhaps some of your readers will agree with me on the following points:

A fortunate minority of women feel no labour pains, or only the final expulsive pains. These patients are not always of the healthy, "open-air" type who might be expected to have a relatively easy labour, nor are they necessarily young or widely built.

Certain local remedies, such as rubbing the back, are well known to be of some assistance. Hot baths may have a wonderful effect. Many patients say that while they are in the bath contractions are felt as strongly as ever, but all the "sting" is taken out of the pains. I have known poor women come into the maternity ward for the benefit of the baths alone, and say that they wished they could have the baby in the bath. Surely this suggests that the pain of labour is local in origin—possibly analogous to cramp, which is also relieved by rubbing and hot baths.

"Doping" the whole nervous system seems to me to be tackling the problem at the wrong end. Investigations to find out the cause of the pain, so widely varying in different subjects, would surely be a better line of attack. We might then, by adjusting the calcium content of the blood, or some other rational means, be able to secure for all parturient women that freedom from pain which is at present accorded by nature to a favoured few.—I am, etc.,

ELISABETH ROLSTON, M.B., Ch.B.

Haslemere, Nov. 23rd.

GASTRIC LAVAGE FOR HYPERCHLORHYDRIA.

SIR,—I desire to advocate a line of treatment in hyperchlorhydria and gastric or duodenal ulcer which, so far as I am aware, in a somewhat limited personal experience, has not received the attention it perhaps merits.

After I had suffered for some two years from chronic indigestion and loss of weight, without, however, any very acute symptoms, a barium meal and *x*-ray photograph, together with the presence of occult blood in the stools, gave evidence of a small ulcer on the lesser curvature of the stomach. A period of some weeks on diet and the usual alkali treatment resulted in the almost complete disappearance of symptoms, and after four or five months' convalescence I achieved normal weight

once more. After that, however, and getting back to work, I began to be bothered with a very troublesome and intractable hyperchlorhydria, as indicated by heartburn, superficial soreness of the chest, occasional pain in the back or front of the chest, discomfort, etc., and, except for a short period after meals, I was rarely free from one or other of these symptoms.

In order to deal with these I went back to large doses of bismuth, chalk, and magnesia, and thereby obtained much relief for a time. Before long, however, the hyperchlorhydria seemed to get worse, and in addition I began to suffer from marked depression and feelings of ill health, due, I became convinced, to the large amounts of the drugs I had to take. I reduced my daily dose of these, with consequently increased trouble from the hyperacidity, although my general state improved.

Finally, after a specially bad week of the most irritating hyperaesthesia of the chest, together with much discomfort and an increasing inability to concentrate on my work, I came to the conclusion that something more had to be done to deal with the matter. It occurred to me that daily gastric lavage might be of material assistance, and I accordingly obtained an ordinary thin rubber duodenal tube and a 20-c.cm. syringe, and began a daily stomach wash-out on getting up in the morning. Although it may not seem so at first sight, yet actually it is the easiest thing in the world to carry out after practising it two or three times. The tube, which has the usual perforated silver strainer at the end, is swallowed with no difficulty, and the stomach contents are drawn off by the syringe and got rid of. The whole operation from start to finish takes only ten to fourteen minutes, and after two or three trial runs it does not worry one in the slightest degree.

My normal procedure is to have my morning cup of tea and a couple of biscuits as usual at 7 o'clock, and then half an hour later, on getting up, to drink a glass of water, either before or after swallowing the tube. I then draw off a pint or more from the stomach. Conceivably, in some cases, mucus might be present in sufficient amount to block the tube, but presumably a dose of sodium bicarbonate in water a short time before swallowing the tube would soften the mucus sufficiently to prevent trouble of this nature. Sometimes, but not often, I have found it necessary to repeat the process about 6 p.m.

The relief gained after commencing the morning lavage was immediate, and I can honestly say the improvement in my condition has been one of 80 per cent.; moreover, it continues. One dose of alkali at night before going to bed is all that I now require, and I see no reason why before long I should not be able, by degrees, to stop both the lavage and the alkali. The treatment has had no effect of an adverse nature on my appetite or in any other way, and I now eat and sleep well.

There is no doubt that the gastric lavage has broken a vicious circle, and has in this way caused the great improvement referred to.

It seems to me that this line of treatment might be of great value in many cases of duodenal ulcer and of healed gastric ulcer or hyperchlorhydria, and in the post-operative treatment of gastro-enterostomy cases, in which hyperacidity is so liable to cause complications. I see no reason why any layman should not carry it out on himself after brief instructions how to do it from his medical attendant.—I am, etc.,

London, Nov. 21st. MEDICO.

DIATHERMY OF THE TONSILS.

SIR,—Dr. Dan McKenzie's interesting article (November 23rd, p. 951) on the coagulation of tonsillar tissue by diathermy leads me to write about my own experience of this treatment.

Some years ago I read *Diathermie et Diathermothérapie*, by Dr. Bordier of Lyons, and since then have treated about fifty cases by the method therein described. Any form of local anaesthesia I have found to be unnecessary as the tonsil is apparently quite insensitive to heat. Of course, one gets an occasional patient who requires cocainization. I have not found it useful to repeat the treatment more often than once a fortnight, for if the whole surface of each tonsil is treated not very deeply at each séance it requires about that time for the coagulum to separate and the deeper tissues to contract, as they undoubtedly do. In about six treatments one can remove most tonsils perfectly cleanly and without any scar formation—results better than those obtainable by the dissection method. The youngest patient in whom I got a satisfactory result was a girl of about 13. I have also had good results in acute follicular tonsillitis. Of course, it is not every patient suffering from this complaint who will submit to the treatment, but in those who will the attacks will be promptly cured. Diathermy appears to me to be the ideal method for destroying the membrane of diphtheria.

A diathermy apparatus is most useful for any medical man. I have had three apparent cures in incipient rodent ulcer, and one in mule-spinners' cancer.—I am, etc.,

Nelson, Nov. 23rd. O. WILSON.

TONSIL AND ADENOID OPERATIONS IN HOSPITAL PRACTICE.

SIR,—I entirely agree with the resolution passed at Manchester on the proposal of Dr. Scott Stevenson. As pointed out by Mr. Watson-Williams, this is no new matter; again and again the position has been brought to the notice of the profession by various authorities. I would go further than some of my colleagues, since I consider that children should be kept in hospital from one day before the operation till three days after—or four days in all.

The root of the whole trouble is that the public, from whom are drawn the lay boards of management of the hospitals, has been taught to regard tonsillectomy as a negligible procedure, instead of as a major operation, whether performed on the child or the adult. This is largely the fault of the medical profession, and some of the letters in the present correspondence will, I fear, help to endorse this view. That is the weakness in the profession: a well-informed portion of it takes a strong stand, but this is undermined by others who state that there is no need for the strength of the stand, so the public concludes that it is only another medical disagreement, and so the "resolution" goes to join its fellows.

Laryngologists should stand together and not let the matter rest until it is put on a satisfactory basis. Let us be adamant that it is "a disgrace to British surgery" that tonsillectomy should be performed as an out-patient operation, and then proceed within our individual spheres of influence, but backed by general approval and support, to bring the matter before the boards of management for action, not opinions or resolutions. There are many operations of general surgery at present performed as in-patient ones which could be treated as out-patient ones with greater safety than tonsillectomy.

The general hospitals are the chief sinners; the special hospitals usually have plenty of beds, comparatively speaking, and their boards are much more sympathetic and helpful. Yet there are those both within and without the profession who are misguided enough to advise amalgamation of the special with the general hospital: a more suicidal policy from the standpoint of oto-rhino-laryngology could not well be imagined.

The shortage of beds for child tonsillectomies is, as pointed out by one of your correspondents, but part of the general shortage for ear, nose, and throat cases, and the existing allocation of beds is quite disproportionate in the majority of hospitals. For the proper administration of any considerable area of population a minimum of thirty beds is required—fifty is desirable; of these a minimum of ten is required for tonsillectomies in children, and if their occupation is arranged in proper rotation a large number of cases can be dealt with.—I am, etc.,

H. NORMAN BARNETT.

Bath, Nov. 23rd.

TREATMENT OF INFECTIONS WITH S.U.P. 36.

SIR,—I must thank Dr. J. S. Hall for giving us further details of his series of "acute mastoiditis" cases treated by means of S.U.P. 36 with such uniform success (November 16th, p. 933). His cases are very interesting, but not, according to my experience, very typical of the commoner forms of the condition. Even in the Case F, chosen as "fairly typical," a temperature of 102° in an adult of 17 years is surely unusual; in fact, a temperature above 99.2° in an adult in which other accompanying causes of such pyrexia—for example, auricular furunculosis or acute dermatitis—can be excluded, surely warrants a suspicion of intracranial complication? I note that in

Case A there is an implied, and as far as I can ascertain novel, claim of relieving even "chronic otitis media." But before S.U.P. 36 is entitled to rank as specific in *otitis media, it will have to prove itself superior* to the conservative measures now usually employed, including the full dose of castor oil.

I *would suggest that the after-history of successfully* treated cases might prove illuminating: it happens not infrequently that the acute signs disappear, hearing returns, *the tympanic membrane clears, and the perforation* may even heal, and yet, after an interval of weeks or months, indefinite symptoms lead to an operation at which is discovered an area of localized, even quiescent, mastoid disease with no apparent connexion with a normal-looking antrum. Will these cases become more common if treatment by S.U.P. 36 comes into vogue?—I am, etc.,

Stoke-on-Trent, Nov. 20th. E. HORACE RICHARDS.

Obituary.

SIR ARCHDALL REID, K.B.E., M.B., C.M., F.R.S.Ed.

THE sudden death from angina pectoris of Sir Archdall Reid, to which a brief reference was made in our last issue, has removed an outstanding personality from the ranks of the medical profession.

George Archdall O'Brien Reid was born at Rooki, India, on April 7th, 1860. His father, Charles Auguste Reid, one of the old "John Company" men, was a captain in the 20th Native Bengal Infantry, H.E.I.C.S. This was the first regiment at Meerut to mutiny, and, with the exception of Captain Reid, who was away at Dehra Dun at the time, all its officers were massacred as they were returning from church. Reid was educated privately, and later spent some years travelling in India, America, New Zealand, and the Pacific. During this period he tried various occupations, among which were those of a prospector, hunter, Kauri gum digger, schoolmaster, and editor. He subsequently went to Edinburgh to study medicine, and graduated M.B., C.M. in 1887. Many years later he was elected a Fellow of the Royal Society, Edinburgh. After obtaining his medical degrees Reid settled in Southsea, where he continued in general practice until the day of his death. He married first Florence, the daughter of the late Colonel John Mahony, C.M.G., and, after her death in 1925, he later married the widow of the late Dr. R. E. Wilmot of Burnham, Bucks.

Although for more than forty years engaged in general practice, Reid's mind was always occupied with the study of scientific subjects rather outside the sphere of routine medical practice, and in particular his name will always be associated with the principles of heredity and the part they play in the evolution of man. On this subject he was a recognized authority, and among his published works are: *The Present Evolution of Man*, 1896; *Alcoholism: A Study in Heredity*, 1901; *The Principles of Heredity*, 1905; and *The Laws of Heredity*, 1910. In 1920 he published a work of a different category, *The Prevention of Venereal Disease*; he also contributed many articles to the *British Medical Journal*, the *Lancet*, *Nature*, and other scientific publications. He had just completed another work dealing with mind, memory, and environment, but death occurred before he had submitted it to a final revision. All Reid's writings were characterized by complete independence and marked originality of thought. He was entirely untrammelled by the weight of authorities or conventional conception, and would accept nothing which his critical mind could not approve. It was inevitable that the views of so fearless a writer should be vigorously challenged, but his profound knowledge of his subject, together with the lucidity and force of his arguments, made him an opponent not to be lightly encountered. Of his published books it is probable that *Alcoholism: A Study in Heredity*, although, or perhaps because, not so highly scientific as some of his other works, most attracted the lay reader. In it Reid maintains that legislative efforts to control drunkenness by restricting the sale of drink can never prove successful. He puts forward the view that alcoholism, or drunkenness, is a disease, analogous to certain zymotic diseases; against it each race must gradually work out its own salvation by the process of evolution whereby such individuals of the race as have an inborn craving for alcohol are gradually eliminated through the effect of their indulgence in it. This argument naturally was strenuously opposed by those temperance advocates who believe that sobriety can be brought about by legislation, and it resulted in numerous controversies in the public press and elsewhere, where Reid more than held his own. His last published work, *The Prevention of Venereal Disease*, was a vehement insistence on the view that the most effective means for the control of venereal disease was the instruction of the public in the adoption of simple methods of self-disinfection after exposure to infection. Reid was medical officer in charge of troops at Victoria Barracks, Portsmouth, during the war, and he asserted that the adoption of the practice of prevention which he advocated had resulted in a greatly reduced incidence of venereal disease among the men under his charge. He was at one time a prominent member of the Society for the Prevention of Venereal Disease, and also president of the Section of Venereal Diseases at the Annual Meeting of the British Medical Association at Portsmouth in 1923.

In his medical practice Read brought to bear the same originality of thought as characterized the development of his theories of evolution. He was constantly adopting such new and unconventional methods of treatment as were suggested to his mind by a study of the pathology and symptoms of the disease which his patient exhibited. As recently as June this year he read a paper at the Royal Portsmouth Hospital describing a method of treatment which he had for some time past been employing with success in cases of chronic arthritis. Working upon the now generally accepted opinion that arthritis is due to chronic absorption of the toxins produced by proteolytic bacteria, he concluded that good results ought to follow the removal of the greatest factory of toxins in the body—namely, the accumulations of decomposing faeces in the colon. The method accordingly which he adopted was daily lavage of the large intestine with a mixture of three parts of normal saline solution with one part of Bulgarian curds, continued until the faecal contents of the colon gave an acid reaction. The patient at the same time was given doses of phenacetin and aspirin thrice daily, and his diet was restricted to vegetables, milk, and milk products. Reid stated that this method of treatment had also proved effective in psoriasis and in certain cases of neuritis. The interest in this paper was considerably enhanced by the exhibition of several sufferers from chronic arthritis, whose symptoms had apparently entirely yielded to the methods described.

To his many friends "Archie," as he was affectionately known, was a most delightful and charming companion. He was a witty and brilliant conversationalist with whom one was never bored, and from whom one seldom failed to hear entirely novel explanations of ordinary commonplace happenings. Simple-minded, hospitable, and sympathetic, he was the most lovable of men. Children he adored, and by them he was loved in return, and it was a terrible grief to him when his only son, Eric, a splendid young fellow, who was idolized by his father, was killed in France at the beginning of 1918. From this blow, borne with characteristic courage, Reid never recovered, hard though he tried to deaden the pain by still closer application to scientific research.

Although a successful general practitioner, and no doctor could have more devoted patients, yet to those who knew him it always seemed a thousand pities that a man of Reid's outstanding ability should be obliged to spend so much of his time in the routine of general practice. Such an original thinker, with so extensive a knowledge of philosophy and science, must have proved a far more valuable asset to his country had he been called to a university chair, where the exercise of his special gifts would have had greater scope and influenced a far wider circle.

A. M. F.

Dr. HENRY JOY CLARKE, J.P., who died at his residence in Doncaster on November 16th, at the age of 62, was the son of Dr. Thomas Clarke of Doncaster, and received his medical education at Edinburgh. In 1878 he graduated M.B., C.M., and obtained the diploma of M.R.C.S.Eng.; he proceeded M.D.Ed. three years later. After holding the posts of house-physician in Edinburgh and house-surgeon to the Glasgow Royal Infirmary, he commenced general practice in 1879 in Doncaster, where practically the whole of his active medical life was spent. He won the high respect and esteem of his colleagues, and recently, at the completion of fifty years of medical practice, was entertained by them to dinner and presented with a testimonial. At about the same time, in recognition of his long service to Doncaster, he received the freedom of the borough. He was for many years a keen member of the British Medical Association, and was unanimously asked to become the first chairman of the newly formed Doncaster Division, a position he held until his death. He was also a member of the Leeds and West Riding Medico-Chirurgical Society, and of the Doncaster Medical Society. A colleague writes: The loss of so worthy a physician is keenly felt in Doncaster, but the influence for good which Dr. Clarke exerted will survive living memory. No one in need or trouble ever sought his counsel or help in vain. He was a man of great personal charm, an ideal family practitioner, and in all respects an ornament to his profession.

Dr. JOHN ALFRED GRAY died at Ealing on November 19th, aged 72. He was educated at St. Bartholomew's Hospital, and took the M.R.C.S. diploma in 1882, and the L.S.A. in 1884. For five years, from 1888 to 1893, he was surgeon to the Amir Abdul Rahman of Afghanistan; and after his return home embodied his Eastern experiences in a most readable book, *At the Court of the Amir*. On his return to England he graduated M.B. at the University of London in 1894, and soon after settled in practice at Ealing, where he was one of the surgeons to the King Edward Memorial Hospital, and also medical officer to the police and post office. He had practically retired from practice for the last two years. He leaves a widow, one son—Dr. John Gray—and one daughter.

Mr. CHARLES HAMILTON WHITEFORD, who died on November 13th, at his residence in Plymouth, received his medical education at St. Bartholomew's Hospital, and obtained the diplomas M.R.C.S., L.R.C.P. in 1892. He devoted himself to surgery from the first, and became well known in the Plymouth area as an operating surgeon keenly interested in the technique of his craft. He was surgical referee to the Plymouth County Court district, consulting surgeon to the Plymouth centre of the Great Western Railway system, and had been honorary surgeon to Plymouth Infirmary, and surgical specialist to the Ministry of Pensions and the Military Hospital, Devonport. Mr. Hamilton Whiteford was for many years an active member of the Plymouth Medical Society, in which he held office as president from 1911 to 1913. He was the author of several publications on surgical subjects, and many years ago built and equipped a private operating theatre.

The death took place in a nursing home at Edinburgh, on November 19th, of Dr. J. M. THOMSON, who had practised in Airdrie for many years. After graduating M.B., C.M. at Edinburgh in 1891, Dr. Thomson began practice in Airdrie, where he remained some thirty-five years. He took an active interest in local affairs, and had been for many years a member of New Monkland parish council. He was also a justice of the peace. He had recently retired from practice, and taken up residence at Polmont.

Dr. D. HAMILTON KYLE, for many years a well-known medical practitioner at St. Andrews, died at Southampton on November 7th. After graduating M.B., C.M. at Glasgow in 1880, Dr. Kyle took up practice in St. Andrews, where he interested himself to a great extent in public affairs, and was for a considerable time a member of the local town council. He is survived by a widow, three sons, and three daughters. Two of his sons and the three daughters, having been brought up at St. Andrews, attained great distinction in the world of golf. Mr. Edward P. Kyle won the championship of the Federated Malay States four times, and played for Scotland against England in 1925. Mr. D. H. Kyle was an international player, and represented Great Britain against America. Each of the daughters has also taken part in international competitions, and reached a high place on various occasions in the Scottish ladies' championship events.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

THE annual general meeting of the Fellows and Members of the Royal College of Surgeons was held on November 21st, with the President, LORD MOYNIHAN OF LEEDS, in the chair. About fifty were present.

The PRESIDENT placed before the meeting the annual report of the Council and drew attention to a number of matters. With regard to the primary Fellowship examination in anatomy and physiology in Canada, he said that this had been from every point of view very satisfactory. It had been decided to hold another examination in Canada in September of next year. The total cost of the examination was £600, and the loss to the College £214. With regard to the British College of Obstetricians and Gynaecologists, he, together with the President of the Royal College of Physicians, had endeavoured to arrange a compromise on the basis of the amendment of certain clauses in the memorandum of the new College, which appeared to be in conflict with the powers and functions of the Royal Colleges. Before this proposal took shape the Council had under consideration the establishment of a special diploma in obstetrics and gynaecology, and this was being proceeded with. In conclusion, he referred to some gifts to the College, including the grant by Lord Beaverbrook of £1,000, which it had been decided to expend on tissue culture research.

In reply to a question by Dr. E. W. D. KITT, the PRESIDENT said that he had never heard any suggestion made to the Court of Examiners that only a certain proportion of the candidates for the Fellowship should be passed. The explanation of the fact that only 92 candidates out of 332 in the primary examination passed, and only 70 out of 225 in the final examination, must be sought in some other direction. To set up an arbitrary restriction of this kind would be contrary to the spirit of the College and also to fair-play. The examiners conducted the examination and reported the results to the Council, who invariably accepted them. In reply to Dr. F. W. COLLINGWOOD, he said that in his belief the examination for the Fellowship was as nearly perfect as any examination could be. It was, of course, impossible to distinguish the all-round surgical capacity of a man except by practice.

Demand of Members for Representation.

The time-honoured resolution affirming the desirability of admitting Members to direct representation upon the Council, in view of the fact that there are 18,587 Members as against 1,945 Fellows, was moved and seconded by Fellows of the College. Mr. SOMERVILLE HASTINGS, the proposer, said that most of those who belonged to the College first became associated with it because they desired to practise medicine. It was only afterwards that they realized that they were part of an active living organism, and desired to be more closely associated with its work. According to the present charter, he realized that the Members had no legal right to the facilities for which they were asking, but he believed they had a strong moral right because of the injustice perpetrated by the predecessors of the Council in the forties of the last century. He believed that at an earlier period the election of the governing body was in the hands of the Members, but when the Fellowship was created it was decided that the governing body should be elected in future solely by the Fellows—in other words, the Council of that day dispossessed the Members of all voice in the control and management of the College. Members had smarted under a sense of injustice ever since. He added that the Members were not dissatisfied with the conduct of the College, and they were putting forward these claims, not because they wanted anything for themselves, but because they felt that they had something to give. Most of the Members of the College were in general practice. In whatever way the medical services of the country might develop, the general practitioner must always be the cornerstone of the edifice, the co-ordinator of medical services. It would always be the duty of the general practitioner to make

provisional diagnosis and determine the surgeon or specialist he should be called in. He could speak the more freely because, he was not himself in general practice when he said that the general practitioners of this country were a body of men and women of whom the country might be proud, and were unmatched by those of any other country. The most important function of the College was in respect to education. Was it not the greatest danger of education that it should become archaic, out of touch with things as they were? This was a danger not remote from medicine and surgery. Were they quite certain that an examinee was not more likely to pass if he was able to give an accurate account, on paper, of how to do a gastrectomy rather than prove himself able to do some of the simpler operations in surgery? The people most likely to prevent these educational or examinational anomalies were general practitioners, in touch with the needs and conditions of practice.

Dr. H. M. STRATFORD seconded the resolution. He pointed to a very general feeling that the manner in which the Members had been deprived of the right of representation on the Council was "mischievous and iniquitous," and both the *Lancet* and the *British Medical Journal*, probably the two most outspoken journals in the kingdom, had not hesitated from time to time to point out the injustice of the position. He went on to say that a vast amount of surgery was in fact done by Members of the College; this was largely, but by no means entirely, minor surgery. In bulk it must far exceed that done by the Fellows. Members were not asking to control the College, but only to be represented by two or three members on the Council. They would bring a decided influence to bear in making the examinations more practical.

Dr. REDMOND ROCHE said that apparently this desirable reform was blocked by the adverse postal vote of 612 Fellows in a body of 20,000 persons. It was these relatively few dissentients which had caused the Council to refrain for the present from proceeding to alter the constitution. Dr. C. W. BROOK, who had on a former occasion supported the resolution, now opposed it on the ground that such a resolution ought not to be brought up year after year, and that the Society of Members should pursue another line, getting a member of Parliament to bring in a private member's bill to alter the Royal Charter. Dr. ARTHUR HAYDON, who also spoke in support of the resolution, suggested that, if there was a technical difficulty, the Members elected to the Council might be created honorary Fellows for the purpose.

The President's Reply.

LORD MOYNIHAN said that Mr. Somerville Hastings's review of the history of the College was quite inaccurate. It was not true that the Fellows had usurped anything from the Members. The Council or Court, before the year that Mr. Hastings gave, was a self-elected body. Nobody but members of the Court had any right to elect members of the Court. It was not a restriction but an extension of the franchise which took place when the College became the Royal College of Surgeons of England. The Members had never had any vote in the administration of the College, and it was just as well not to base any arguments on entirely erroneous historical statements. This was the forty-first occasion on which a similar resolution had been brought forward, and again the statement was made that general practitioners required representation on the Council. Was it not obvious to anybody who gave a few moments' consideration to the subject that the large bulk of the Fellows of the College were in general practice—at least 80 per cent. of them? The Council was elected by a majority of general practitioners, and not by specialists. Yet this same argument had been used for the fourth year to his own knowledge. The cause of the Members was not advanced by time-worn and misleading arguments. During the forty years in which this resolution had been brought forward had any enthusiasm for it been generated among the general body of the Members? He had never discovered any evidence to that effect. Those bringing forward the resolution had never shown that they carried the bulk or even a reasonable proportion of the Members with them.

A MEMBER: They are too busy to bother about politics.

LORD MOYNIHAN: I quite agree. They do not even come in any large numbers—much to my regret—to this annual meeting. Somebody raised the question of examinations. We do take steps to alter the character of the examinations, but those steps have to be taken so gradually that even those who follow the examinations closely cannot exactly say when the change takes place. We might determine, for example, that the primary examination should deal far more with functional than with ordinary descriptive anatomy, but to make such a change suddenly would be very unfair to the man who has spent perhaps eighteen months in preparing for the examination. Anyone who compares the examination of to-day with that of ten or fifteen years ago, however, will be aware of a slow but definite change in character. The examination has been brought more into line with the needs of the present time. Let me add this, that I come here with the desire to give the most cordial welcome to the Fellows and Members who care to attend this meeting. It is the Members' College just as much as the Fellows', and Members are most cordially welcomed here. But we exist under a charter, which requires us to do certain things in a certain way. If the Members have any urgent desire for the alteration of that charter I am sure they will be able to get it altered. But no evidence of this has been brought to my knowledge, and I am at least as deeply interested in this matter as anyone else here.

A MEMBER: Would the Council take a postal vote?

LORD MOYNIHAN: The Council is prepared to consider any representation made either by a body of representative Members or by individual Members. You must get out of your minds the idea that there is the smallest hostility on the part of the Council. We are here individually and collectively of set purpose to support your interests.

Dr. RICHARD LLOYD said that whatever might be the case to-day when the Members were disappointed by repeated rebuffs, there had been occasions in the past when the enthusiasm for this resolution was so great that the gates of the College had to be closed against the press of Members.

Mr. SOMERVILLE HASTINGS said that if he had inaccurately described the former procedure it was not for want of care. He had gone closely through the charter of 1800, and it certainly appeared to him that the Members of the College then elected the governing body. LORD MOYNIHAN repeated that it was a self-elected body. He was very willing to go into the documents with Mr. Hastings.

Dr. REDMOND ROCHE thought that what Mr. Hastings had said was accurate as applied to the year 1785, prior to the incorporation. LORD MOYNIHAN: That is irrelevant. It was not the Royal College of Surgeons before 1800.

The resolution moved by Mr. Somerville Hastings was then carried by 44 votes against 2, and the PRESIDENT said that he would, as before, see that the message was duly conveyed to the Council.

UNIVERSITY OF CAMBRIDGE.

THE Raymond Horton Smith Prize, awarded to the candidate who presents the best thesis for the M.D. degree during the academical year, has been awarded to Wilfred Shaw, M.D. (St. John's).

UNIVERSITY OF LONDON.

EARL BEAUCHAMP was installed as Chancellor of the University of London on November 22nd. Dr. Scott Lidgett acted as vice-chancellor in the absence of Sir Gregory Foster, and conferred upon Earl Beauchamp the honorary degree of Doctor of Literature.

Dr. G. A. Harrison has been appointed, as from October 1st, 1929, to the University Readership in Chemical Pathology, tenable at St. Bartholomew's Hospital.

Sir Cooper Perry has been appointed a member of the board of management of the London School of Hygiene and Tropical Medicine, and Mr. H. L. Eason, M.D., M.S., chairman of the Library Committee.

LONDON HOSPITAL MEDICAL COLLEGE.

Liddle Triennial Prize.

The subject of the Liddle Triennial Prize for 1929-30, value £120, is the cause and incidence of duodenal ulcer. Essays for the prize, which is open to public competition, must be delivered at the hospital not later than 4 p.m. on May 31st, 1930. A printed copy of the conditions under which it will be awarded may be obtained from the dean of the London Hospital Medical College, Mile End, E.1. The prize essay, and every accompanying drawing and preparation, will become the property of the trustees of the fund out of the income of which the prize is given, but permission for publication will not be withheld.

The object of the prize being to encourage original observation and investigation, no award will be made when, in the opinion of the examiners, the essays have not attained a sufficiently high standard of excellence. The award will be made within six months from the date of sending in the essays.

UNIVERSITY OF SHEFFIELD.

Lectures on Cancer.

THE Clinical Medical Studies Committee of the University of Sheffield has arranged, in conjunction with the Yorkshire Council of the British Empire Cancer Campaign, for three lectures on cancer, to be given at the University during the coming winter. The first of these lectures will be delivered on December 3rd by Dr. Maurice Davidson, physician to the Miller General Hospital and the Brompton Hospital for Consumption, on intrathoracic and pulmonary new growths; it will be illustrated by lantern slides and pathological specimens. Professor Arthur Hall will take the chair at 8 45 p.m. All medical practitioners are cordially invited. Particulars of the two lectures to be given after Christmas will be announced shortly.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE following candidates have been approved at the examinations indicated:

FINAL MEDICAL EXAMINATION — *Part II. Medicine*: E. F. St. J. Lyburn, A. R. Johnston, A. Rose, Josephine M. Enright, Lilla M. Spiller, W. B. Hamilton, D. G. M'Cauly, W. A. Y. Knight, F. O. Pilkington,

A. J. Garde, G. F. West, Dora G. Bradley, R. P. M'Garrigle, A. Rakoff, R. E. Hemphill, F. M. Lyons, F. S. Mackenna. *Surgery:* *G. B. Thrift, G. R. Beare, Kathleen A. Wilson, E. S. Tweedy, M. E. Kirwan, G. K. Graham, E. J. M. Bam, J. N. U. Russell, Frances E. Wilson, Dora G. Bradley, J. F. K. MacCarthy-Morrogh, J. M. M'Elligott. *Midwifery:* *A. H. Thompson, *P. L. O'Neill, *R. Bowesman, *J. M. Gibbon, D. Nolan, F. P. FitzGerald, Annie E. Thompson, T. H. Dockrell, H. R. O. Dorman, D. G. M'Caully, A. A. Lisney, J. T. Robinson, Ruth R. Armstrong.

M.Ch.—J. C. Fouché, H. E. Murray.

* Passed on high marks.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

At the annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, held on November 4th, Dr. John F. Fergus was elected President in succession to Mr. G. H. Edington. The other office-bearers appointed are: Visitor, Mr. R. Barclay Ness; honorary treasurer, Mr. J. H. MacDonald; honorary librarian, Dr. E. H. L. Oliphant. The representative on the General Medical Council is Mr. Edington, and the councillors are Professor J. M. Munro Kerr, Mr. Thomas Kay, Mr. John Patrick, Mr. R. M. Buchanan, Mr. J. Galbraith Connal, Dr. C. C. Douglas, Dr. John Gracie, Mr. Andrew Allison, Dr. J. Souttar McKendrick, and Mr. W. Ferguson Mackenzie. It is worthy of note that Dr. J. F. Fergus's father and his brother, Dr. Freeland Fergus, served as Presidents of the Faculty.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

Surgery.—W. J. D'Rosario, I. F. W. Edwards, W. J. Frith, B. C. Ghose, W. A. R. Mailer, I. W. H. Mansfield, E. J. O'Loughlin, S. Ramadas.

Medicine.—R. Gilmore, J. Gordon, M. Naylor, A. Scher, L. J. P. Sonomenho.

Forensic Medicine.—J. Britanischski, R. F. M. Child, A. Kellner, E. E. Le Feuvre, M. Naylor, A. Scher, L. J. P. Sonomenho, G. W. Sturgess.

Midwifery.—P. S. Balachandran, K. C. Bhattacharyya, A. Buch, W. J. D'Rosario, I. F. W. Edwards, A. D. H. Hugo, T. C. Keble, W. A. R. Mailer, C. G. Nicol, D. Ram Annamalai.

The diploma of the Society has been granted to Messrs. P. S. Balachandran, K. C. Bhattacharyya, R. Gilmore, and E. J. O'Loughlin.

The Services.

QUEEN ALEXANDRA MILITARY HOSPITAL.

Opening of New Wing by the Prince of Wales.

A new wing of the Queen Alexandra Military Hospital, Millbank, was opened on November 26th, by H.R.H. the Prince of Wales. The new building, which has cost £28,000 and has been erected in nineteen months, is on the eastern side of the main hospital, houses all the special departments; and affords provision for out-patients; it contains no beds. On the ground floor are the dental, dermatological, and special surgery departments; on the first floor the radiology and massage departments, and the pathological laboratories; and on the top floor the departments of ophthalmology and for ear, nose, and throat cases. Up to now these departments have been accommodated in the main building, but the demand for hospital space has been such as to make this no longer convenient. Advantage was taken of the building of the new wing to house and equip the various departments on up-to-date lines, and the general provision and lay-out was the subject of admiring comment by visitors.

The opening ceremony was marred by bad weather, which led to the abandonment of the outdoor proceedings: but in any case only an informal occasion had been planned, and no set speeches were made. The Prince, after a number of presentations, inspected each of the departments in turn, and also visited one of the wards of the hospital.

The Prince, on arrival, was received by General Sir Walter Braithwaite, Adjutant-General, General Sir Robert Whigham, Commander-in-Chief, Eastern Command, and Major-General C. E. Corkran, general officer commanding London District. Lieut.-General H. B. Fawcus, Director-General Army Medical Services, was presented, and he in turn presented, among others, Brevet-Colonel Ryan, officer commanding the hospital, Miss R. Osborne, matron-in-chief, War Office Miss L. E. Mackay, matron of the hospital, Colonels Harrison, Kennedy, and de la Coeur, consultants, and the following members of the honorary civil consulting staff: Mr. Victor Bonney, Mr. F. D. Davis, Sir Crisp English, Professor E. H. Kettle, Sir W. Lister, Lieut.-Colonel H. MacCormac, Colonel A. G. Phear, Dr. S. Gilbert Scott, Sir John Thomson Walker, and Colonel A. E. Webb-Johnson.

The heads of each of the departments visited were presented to the Prince as follows: Captain S. H. Woods (dental), Major J. H. Frobisher (surgical out-patients), Major F. C. Doble (dermatology), Lieut.-Colonel D. S. Skelton (pathology), Major R. M. Dickson (ophthalmology), Major J. Hare (otology), Major E. V. Whitby (radiology), and Miss V. M. Macdonald (massage).

The Prince left after a stay of half an hour, and subsequently the commandant and officers of the R.A.M.C. Headquarters Mess entertained at an "at home" a large number of visitors.

DEATHS IN THE SERVICES.

Surgeon Lieut.-Commander Gilbert Malise Graham, R.N. (ret.), died of pneumonia, after a long illness due to war service, on November 9th. He was the only son of the late Joseph Graham, M.A., of Edinburgh, and was educated at Edinburgh University, where he graduated as M.B. and Ch.B. in 1911. Entering the navy on April 3rd, 1914, six months later he was posted to H.M.S. *Emperor of India*, flagship of Rear-Admiral A. L. Duff, in the Grand Fleet. In September, 1916, he was appointed to the Naval Hospital, Malta, and served there till the end of the war. In February, 1920, he was posted to H.M.S. *Truro*, in the mine-sweeping flotilla. He was promoted to surgeon lieutenant-commander in that year, and retired, owing to ill health, on April 3rd, 1921.

Colonel Thomas James Hackett Wilkins, Madras Medical Service (ret.), died at Mongeham Lodge, Great Mongeham, near Deal, on November 15th, aged 79. He was born on October 6th, 1850, at San Thomé, Madras, the son of the late Thomas Wilkins of the Registrar's Office, High Court, was educated at Edinburgh, and took the Licence of the Scottish Colleges in 1875. Entering the I.M.S. as surgeon on September 30th, 1873, he attained the rank of colonel on June 30th, 1905, and retired on June 30th, 1908. He served in the Burma campaign of 1885-86, with the Tunghu-Nyaingyan column, took part in the storming of Aylak, and the action at Neybeyagown, and received the medal with a clasp. He received the C.B.E. on January 1st, 1920, for service at home in the late war.

Lieut.-Colonel Christian Bernard Hunter, Bengal Medical Service (ret.), died at Sharcot House, Pewsey, Wilts, on November 13th, aged 77. He was born on December 8th, 1851, the son of the Rev. Thomas Hunter of Chesterfield, Derbyshire, was educated at University College, London, and took the M.R.C.S. in 1877 and the L.R.C.P.Lond. in 1878. Entering the I.M.S. as surgeon on March 31st, 1879, he became lieutenant-colonel after twenty years' service, and retired on April 15th, 1900. He spent all his service as a regimental surgeon. He served in the Afghan war of 1878-80 (medal), and on the North-West Frontier of India in the Zhob Valley expedition of 1890, and in the two Miranzai campaigns in 1891 (medal with clasp).

Medical Notes in Parliament.

[From our Parliamentary Correspondent.]

Early in the week the text of the Government's Mental Treatment Bill (referred to elsewhere at page 1019) was published in readiness for a second reading debate on it in the House of Lords on November 28th.

On November 25th the House of Commons read the Unemployment Insurance Bill a second time. A long debate in committee on the Expiring Laws Continuance Bill delayed next night the discussion on the second reading of the Highlands and Islands (Medical Service) Additional Grant Bill. On November 28th the Committee stage of the Unemployment Insurance Bill was due to begin.

The Parliamentary Medical Committee met on November 26th, Dr. Salter presiding. The Committee decided to discuss, on a later occasion, milk, and the presence of tuberculosis in milk. It further agreed to discuss incipient insanity, at its next meeting on December 10th, when a medical officer from the Board of Control will be invited to attend. At this meeting, on November 26th, the Committee was addressed by Sir George Newman, chief medical officer of the Ministry of Health, and by Dr. Hutchinson, head of the Infectious Diseases Department of the Ministry. These spoke on the present position of small-pox and vaccination in England and Wales, the incidence of the disease, its mortality, and its relation to encephalitis. The Committee then discussed the desirability of compulsory vaccination, but there was no attempt to take any decision.

The Medical Committee is visiting research institutions near London this week.

Milk in the Dietary of Children.

On November 26th Dr. ELLIOT asked leave to introduce the Education (Scotland) Bill, to enable education authorities in Scotland to incur expenditure in supplying milk to children attending schools within their area. He said that it had been clearly shown during the last few years that, although a diet might be adequate in amount and might even contain all that was supposed to be necessary to produce a healthy full-grown creature, yet, if small quantities of certain substances were lacking from that diet a growing creature—be it child or animal—would not reach full maturity. The work done on what were known as vitamins was a striking example of that. On the lines of experments carried out in the United States of America and elsewhere, experiments had been made into the value of adding a small quantity of milk to the daily ration, first of all of animals and afterwards of growing children. Very interesting and remarkable results had been obtained. These experiments were carried further in this country by the Medical Research Council, which, in 1926, made a series of tests on boys under more or less controlled conditions and under the management and scientific supervision of Dr. Corry Mann. Those tests showed quite clearly a remarkable increase in growth, health, and even in the intelligence of the growing children who received the daily ration of milk.

The Scottish administration, with which he (Dr. Elliot) was then associated, brought the results of the experiments to the notice of the Empire Marketing Board on the ground that they should apply them in Scotland and elsewhere in the United Kingdom as affording an admirable chance of encouraging the use of home produce. In the case of fresh milk, the home producer had a preference and advantage over other producers of which it was impossible to deprive him. Thus, in this connexion, an opportunity was afforded of improving the health of the nation and of stimulating home production, especially in the field of agriculture. Accordingly a grant was made from the Empire Marketing Board, and tests were conducted over a period of two years. In 1926 and 1927 really striking and remarkable results were obtained. It was thought desirable not to publish those results at once, but to verify them by repeat tests. The tests were carried out in seven Scottish centres of population—Peterhead, Aberdeen, Dundee, Edinburgh, Glasgow, Greenock, Paisley, and also in Northern Ireland in the city of Belfast. Two thousand children were under observation. They were under full scientific supervision, conducted, in the first instance, by Dr. Orr of the Rowett Institute and Dr. Cruickshank of the Board of Health; and, in the second instance, by Dr. Leighton and his assistants of the Board of Health, now the Department of Health for Scotland.

The results of these tests showed that a small ration of milk added to the diet of the ordinary school child in Scotland during seven months increased the height of the children who received it by a quarter of an inch, and their weight by three-quarters of a pound. An additional biscuit ration which was given as an alternative to the additional milk did not lead to any increase in growth, either in height or in weight, over the children who received no additional ration at all, which seemed to point quite clearly to the fact that those children were receiving sufficient food, but they were receiving food which was deficient in some respects, and the making up of that deficiency by a small ration of milk produced this surprising result of greater growth in height, increase in weight, and improvement in health. All observers said that there was a sleekness of the hair, a polished condition about the nails, and a certain boisterousness and a rebelliousness about the children on the milk diet which was not found in the children receiving the biscuit diet. The children were of all ages from 5 to 6 up to 13. This applied not merely to necessitous children, but to practically all children, and therefore it seemed that it was scientifically proved that the diet of the ordinary child could be greatly improved by a small alteration of quality. Milk occupied a position somewhere between a drug and a food, and a great many parents who came under no definition of necessity might reasonably find that by working in with a scheme of a local authority they could, either on payment of a proportion of the cost, or on payment of all the costs, ensure a great improvement in the health of their children.

The bill would have the immediate effect of modifying the rigid provisions requiring and demanding recovery of all the costs and the supply only in cases where the parent was proved to be absolutely negligent in his care of the health of his child. The cost of those things ran to something like 1d. per child per day. That was the full cost, but he did not suppose for a moment that the full cost in the case of every child would be borne by the local authority. He could not imagine any better form of investment, nor anything that would be of more immediate value to a child's chances in life. If they could make a healthy child he was certain that it would pick up a great deal of its own education, whereas an unhealthy child might receive no advantage from the most careful schooling they could possibly give it. They had other experiments of a converging kind, proving the benefit of this one. They were able to carry out a certain amount of milk feeding in Africa, where the same criticism of boisterousness and even of rebelliousness was brought against the children who had the milk ration.

The bill proposed that a local authority could incur expenditure on milk by submitting a scheme for the approval of the Departments of Health and of Education.

Leave was given to introduce the bill, which was brought in and read a first time.

National Insurance.

Medical Benefit.—Mr. MANSFIELD asked the Minister of Health, on November 21st, whether he proposed to amend the National Health Insurance Act to enable approved societies to get financial assistance towards the cost of any form of treatment—benefit or otherwise—which a member of less than five years' membership might require. Mr. GREENWOOD replied that an approved society which was found on valuation to have a disposable surplus might adopt a scheme for contributing towards the cost of dental, ophthalmic, hospital, or convalescent home treatment required by its members. The qualifying period from January next will be reduced to two and a half years on the average, as against five years in force hitherto.

Obligations of Panel Doctors.—Mr. ISAACS asked, on November 21st, whether members of approved national health insurance societies were often inconvenienced by panel doctors declining to issue a second certificate before the expiration of seven days following the first. He asked Mr. Greenwood to draw panel doctors' attention to the *Medical Benefit Consolidated Regulations*, 1923, which provided that the doctor, on request, should give the insured person, if still incapable of work, a second certificate not later than the seventh day after the first certificate. Mr. GREENWOOD said that he had not received any representations to this effect. Attention was frequently drawn to the obligations of panel doctors.

Dangerous Drugs.

Mr. CLYNES, replying to a question on November 25th, said that, after the coming into force of the Dangerous Drugs Acts, no cocaine was manufactured in Great Britain until 1928, when 1,047 ounces of cocaine and 3,887 ounces of the salts of cocaine were manufactured under Home Office licence.

Mr. Clynes told Mrs. Hamilton that the Health Committee of the League of Nations estimated (but with some qualifications) that in countries possessing a highly developed system of medical assistance the maximum requirements of opium and its alkaloids and derivatives for medical and scientific purposes were, in terms of raw opium with 10 per cent. morphine, 450 mg. per head per year, and of cocaine 7 mg. per head per year. Upon the basis of this calculation, and with an estimated population of 45,625,000, the maximum requirements of Great Britain and Northern Ireland were, in 1928, 45,263 lb. of raw opium and 704 lb. of cocaine. The quantities manufactured in Great Britain in 1928 of the drugs to which the Dangerous Drugs Acts applied were: 6,859 lb. of medicinal opium; 9,056 lb. of morphine and its salts, including 4,868 lb. used in the manufacture of derivatives of opium or morphine which were not within the Dangerous Drugs Acts; 675 lb. of diacetylmorphine and its salts; 308 lb. of cocaine and its salts. The quantities exported in 1928 were: raw opium, 15,955 lb.; medicinal opium, 3,394 lb.; morphine and its salts, 3,114 lb.; diacetylmorphine and its salts, 377 lb.; and cocaine and its salts, 278 lb. Figures were not available in regard to opium derivatives, which were not subject to the provisions of the Dangerous Drugs Acts.

In 1928-29 48,854 acres were under opium cultivation in British India, and 6,778 chests were exported, value 27,112,000 rupees.

Trypanosomiasis.—On November 20th Mr. LUNN said, in reply to Dr. Morgan, that the International Sleeping Sickness Commission appointed by the League of Nations for work in Uganda completed its work in June, 1927, and published its final report in March, 1928. An international conference held in Paris a year ago recommended that lines of investigation opened up by the Commission should be followed up by Governments concerned, with their own resources. Sleeping sickness problems were being investigated in Tanganyika, Nyasaland, Nigeria, and the Gold Coast as well as in Uganda.

Rheumatism in Children.—Dr. Davies was informed by Mr. GREENWOOD on November 21st that grants were available under the Maternity and Child Welfare Regulations for the experimental investigation and treatment of acute rheumatism in children under school age. Mr. Greenwood was advised that this disease was rare among young children. The Board of Education paid grants for similar purposes in the case of children of school age, and the Medical Research Council made grants for researches into rheumatism. Dr. FREMANTLE asked whether the efforts of the three departments concerned had been co-ordinated. He was told that they were within the knowledge of the three Ministers.

Encephalitis Lethargica and Crime.—Mr. CLYNES told Mr. Sorensen, on November 21st, that when persons thought to be suffering from encephalitis lethargica came before a criminal court a report on their medical history and present condition was made to the court. The decision on the action taken rested with the court. Replying further to Dr. Vernon Davies, who asked whether any steps were taken to inquire into previous medical history, Mr. Clynes said his answer implied that something in the nature of a medical history was brought into court.

Diseased Meat.—Replying to Mr. Kedward, on November 21st, Mr. GREENWOOD said he could not state the number of diseased carcasses of imported meat which were condemned as unfit for human consumption. He thought the present regulations sufficient to protect the public against the importation of diseased meat.

Tuberculous Milk.—Mr. GREENWOOD told Sir Rennell Rodd, on November 21st, that he was satisfied that local authorities exercised their powers of supervision and control over milk supplies in an efficient manner, having regard to the difficulties caused by the mixing of milk and the delays necessary in obtaining reports on the bacteriological examination. Infants' deaths from bovine tuberculosis traceable to milk would nevertheless continue to receive his careful attention. Dr. Davies thereupon asserted that bacteriological examination of milk for tubercle was hopelessly inadequate in England.

Adulteration of Milk.—Mr. GREENWOOD, on November 25th, stated that during 1928 the Ministry of Health corresponded with nineteen local authorities about the adequacy of the numbers of samples of milk taken for the purpose of checking adulteration. From most of these a sufficient explanation was forthcoming or arrangements had been made for more samples to be taken.

Preparation of Government Lymph.—Replying to Mr. Freeman, on November 21st, Mr. GREENWOOD said that Government lymph for vaccination was prepared at the Government lymph establishment at Hendon, and that 438 calves and 38 rabbits were used in its preparation in 1928.

Expert Medical Visitors to the Colonies.—On November 20th Mr. LUNN told Dr. Morgan that medical experts who had visited the Colonies during the last few years included Sir Wilfred Beveridge (Bahamas and other West Indian Islands), Dr. A. E. Horn (Cyprus), Dr. J. Hope Reford (Falkland Islands), Dr. A. T. Stanton, Chief Medical Adviser to the Secretary of State (Nigeria, Gold Coast, Sierra Leone, and Gambia); Lieut.-Colonel S. P. James (Kenya, Uganda, and Tanganyika). Mr. Lunn added that the reports of Sir Wilfred Beveridge and Dr. Horn were available, as the report of Colonel James would shortly be. This last was specially concerned with malarial problems. A commission of the League of Nations recently investigated the health problems of the Western Pacific Islands, and their report would soon be published. Mr. Lunn further told Dr. Morgan that the International Health Division of the Rockefeller Foundation continued to co-operate with the local medical authorities in investigations into yellow fever in Nigeria and other West African colonies. It also co-operated in malarial surveys in West Indian and Western Pacific Islands and in Palestine. Mr. Lunn hoped to extend the system of malarial surveys in co-operation with this organization.

Sleeping Accommodation in Public Mental Hospitals.—On November 19th Miss LAWRENCE, replying to Mr. Sorensen, said that on January 1st there was sleeping accommodation in bed space as prescribed by the Board of Control for 48,980 males and 60,649 females in public mental hospitals in England (excluding Monmouth). There were 47,902 male and 61,288 female patients resident. In Wales (with Monmouth) there was accommodation for 3,148 males and 3,015 females, and 3,362 males and 3,208 females were resident.

War Pensions.—On November 25th several questions were put to the Minister of Pensions concerning the new concessions to ex-service men who claim after the expiry of the seven years' limit. Answering Major Cohen, Mr. F. O. ROBERTS said he did not think it practicable or desirable now to define minutely the procedure on applications for pensions outside the limit. All applicants would be expressly invited by the area offices of the Ministry to state their cases in writing and to furnish evidence in support. Free use would be made of the advice of the independent medical experts nominated by the Presidents of the Colleges of Physicians and Surgeons in all cases where there was material conflict of evidence, including cases recommended after investigation by War Pensions Committees. The fullest weight would be given to the advice of these experts. He was, however, unable to bind himself to accept their opinion in every case. War Pensions Committees would, as far as possible, be made acquainted with the grounds for rejection of any case recommended by them, after investigation.

Refuse Dumps.—In an answer to Major Llewellin and Mr. Muggeridge, on November 21st, Mr. GREENWOOD said he had no power to compel local authorities to have refuse dumps covered. Replying to Dr. Fremantle, Mr. Greenwood said he had appointed Mr. Ernest Sanger to be chairman of the Departmental Committee of inquiry into the whole question of refuse disposal in the London area.

Pollution of Rivers.—The Joint Advisory Committee on River Pollution is particularly considering measures to prevent pollution by trade effluents.

Medical News.

THE annual dinner of the Yorkshire Glasgow Graduates' Association will be held in the Great Northern Hotel, Leeds, on Friday, December 6th, at 7 p.m. All graduates resident in Yorkshire or the surrounding areas are eligible for membership and are invited to the dinner. The guest of the evening will be Professor J. Graham Kerr, M.A., F.R.S. Further information may be obtained on application to the honorary secretary, Dr. W. MacAdam, 40, Park Street, Leeds.

THE annual meeting of the Royal Surgical Aid Society will be held at the Mansion House, London, on Tuesday, December 3rd, at 4 p.m., under the presidency of the Lord Mayor.

THE fifth lecture of the People's League of Health new series on racial and individual welfare will be delivered to-day (Friday, November 29th) at the house of the Medical Society of London, Chandos Street, W., at 6 p.m., by Dr. R. G. Gordon; his subject is, "What the State is doing for the individual and the race, and how such efforts may be amplified."

THE Fellowship of Medicine announces that a lecture, entitled "Aches and pains in the throat," will be given by Mr. Harold Kisch in the lecture room of the Medical Society of London, 11, Chandos Street, W.1, on Monday, December 2nd, at 5 p.m.; the lecture is free to medical practitioners. On Tuesday, December 3rd, at 8.30 p.m., Dr. Kinnier Wilson will lecture on fits; their varieties, pathogenesis, and relation to narcolepsy, catalepsy, syncope, etc. On Friday, December 6th, at 8.30 p.m., Dr. Knyvett Gordon will give, at 10, Bedford Square, W.C.1, the last of the M.R.C.P. special course lectures arranged by the Fellowship of Medicine; his subject, "The diagnosis of bacterial infection," will be illustrated by the epidiascope, and the lecture will be followed by a laboratory demonstration. The following three special afternoon courses will begin on December 2nd, each lasting for two weeks: a course at the Infants Hospital, of interest to those engaged in infant welfare work; an afternoon course in dermatology at the Hospital for Diseases of the Skin, Blackfriars Road; and a general practitioners' course at the London Temperance Hospital, from 4 to 5.45 o'clock. Detailed syllabuses of all courses, the list of special courses for 1930, and particulars of the general course, consisting of the clinical practice of the associated hospitals, may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A COMMEMORATION service in connexion with the 150th anniversary of the General Hospital, Birmingham, will be held at the Cathedral Church, Birmingham, on Tuesday, December 10th, at 12 noon, when the Archdeacon of Ludlow (Dr. Edwin B. Bartleet) will preach. At 2.15 p.m. on the same day Sir Gilbert Barling will take the chair and orations will be given in the out-patients' hall of the hospital by Professor K. F. Wenckebach of Vienna and Lord Moynihan, president of the Royal College of Surgeons of England. Past and present students of the Birmingham Medical School are invited to be present; academic dress will be worn.

FOR some considerable time there has been a hostel at 22, Highbury Quadrant, which has been conducted in association with the Royal Free Hospital for the treatment of pregnant women suffering from venereal disease. The work has been so successful that it has been found necessary to acquire the adjoining house, and to equip it for the same purpose at a total cost of nearly £4,000, of which over £2,700 has been received in the form of donations. The new hostel was formally opened on October 28th, by Lord Riddell, president of the Royal Free Hospital, who delivered an address on the connexion between hospitals and hostels. Dr. Letitia Fairfield also gave a lecture on the place of voluntary work in the venereal diseases scheme.

THE Ministry of Health has issued the report of a committee representing various public bodies which was appointed some time ago to discuss the question of technique in carrying out chemical analyses of sewage and sewage effluents. The report (price 2s. 6d., H.M. Stationery Office) is designed to assist those who are engaged in testing the purity of effluents from sewage disposal works and rivers. It deals with: (1) methods for carrying out tests for sewage and sewage effluents and methods of expressing results; (2) tests to be included in all analyses; (3) tests appropriate for use at small sewage works. The Royal Commission on Sewage Disposal, which sat from 1898 to 1915, did a large amount of work on methods of analysis, and in suggesting the best methods which might be adopted the present committee has built upon that work.

AN international exhibition of hygiene, in which nineteen countries will be represented, will be opened at Dresden on May 17th, 1930.

UNDER the chairmanship of Major-General Sir William ..., members of the Irish Medical Schools' and ... Association and their guests dined together at the Savoy Hotel, London, on November 21st. After the loyal toasts had been honoured, Dr. W. J. Corbett proposed the ... of the visitors, making special reference to Sir John ... Lady Lavery, and to Lord Shannon, who were the guests of the evening. In the modern renaissance of art, he said, Irishmen were playing no small part: George Bernard Shaw ...s an Irishman; so was George Moore, the greatest living ... of English prose. In painting, Ireland was repre-...ted by Orpen, Jack Yeats, Shannon, and their distin-... guest, Sir John Lavery. He could never despair of the present age when he remembered that it had produced such men as these, creators of beauty, whose work enriched not only our lives but would enrich the lives of generations yet to come. In reply Sir John Lavery said that artists had much in common with doctors. Both were subjected to much criticism, and everybody felt competent to teach them how they should really do their jobs. One of his first commissions, he said, had been to paint the portrait of a well-known throat specialist, himself a painter of some distinction, and at a certain stage of the work he asked the specialist for his comments. "I never permit my patients to prescribe for me," replied the specialist. This wise remark, said Sir John, had influenced him deeply; he never allowed his patients to prescribe for him. Dr. W. P. Kennedy, in proposing the toast of "The President and Association," said that although the association had been founded fifty-one years ago, three of the original members were still living. By its means Irishmen in England were able to meet together in good fellowship, to form valuable friendships, and to help each other as compatriots should. The association had been a pioneer in admitting women guests to its dinners and women graduates to its fellowship. The President, in his reply, reminded his audience that Colonel James Henry Reynolds, late of the Royal Army Medical Corps, the senior V.C. in the Army, was an Irishman, and that in India they were proud to have two Irish Generals, both of whom were V.C.'s. During the evening Mr. Patrick Hughes, Miss Eileen Ledlie, Miss Agnes MacHale, and Miss Ballam provided an attractive musical programme.

DR. WILLIAM FOSTER, who has been medical officer of health for Shipley for the past thirty-four years, and has just retired, was entertained to dinner at the Victoria Hotel, Bradford, on November 20th, by the medical practitioners of Shipley and Baildon, when he was presented with an inscribed silver bowl. Dr. Foster has been a member of the British Medical Association for many years, and has won great popularity by the way in which he has co-operated closely with general practitioners in the advancement of public health.

THE tenth Belgian Congress of Neurology and Psychiatry will be held at Liège under the presidency of Professor X. Francotte on July 26th and 27th, 1930, when the following subjects will be discussed: angioneuroses, introduced by MM. Divry and Moreau of Liège, and congenital disturbances of speech, introduced by M. Jacques Ley of Brussels. Further information can be obtained from the secretary, Dr. Leroy, 30, Rue Hemricourt, Liège.

WE have received from the dental unit of the Papworth Village Settlement the report of an investigation by Dr. L. B. Stott and Mr. W. Baird Grandison into the effect of toxaemia on enamel formation. The subjects of investigation were the tuberculous adults living in the Settlement, children with tuberculosis or with a tuberculous history, and 40 children born in the Settlement of tuberculous parents but themselves free from the disease. The authors conclude that calcification and decalcification depend on factors associated with metabolic changes resulting from toxaemia; that toxaemia occurring at a time corresponding to the calcification of enamel will check that process and result in the production of hypoplasia, and that a renewal in the activity of an infective disease will cause a corresponding breakdown of enamel, with subsequent caries. Sir Humphry Rolleston, who contributes a preface, commends the critical acumen with which the work has been carried out, and expresses the hope that the authors will publish further observations on the influence of tuberculosis on the development of teeth.

DR. HERMAN LAWRENCE has published a sequel to his article on the relation of prolonged sunshine and atmospheric humidity to the prevalence of skin cancer in Australia; we commented on his conclusions on January 19th (p. 119). His second article is published in the *Health Bulletin*—a quarterly journal issued by the Australian Commission of Public Health—and in it a comparison is drawn between the conditions in this respect in the United States of America and those in Australia. Dr. Lawrence pleads for more prompt treatment of the early manifestations of chronic solar irritations, particularly of the hyperkeratoses, and he recommends the use of the Grenz rays, salicylic acid, and a modification of Darier's quinine application.

THE Health and Cleanliness Council has recently published as a booklet a propaganda play entitled "The Giant Killer," which has been written by George and Una Bence with the aim of imparting hygienic instruction in a form palatable to young children. The booklet contains music for the songs and dance which are included in the play, together with simple notes on costumes and production. Copies of the play may be obtained, free of charge, on application to the secretary, Health and Cleanliness Council, 5, Tavistock Square, London, W.C.1.

THE November issue of the *Deutsche Zeitschrift für Chirurgie* has been dedicated by the editor and publishers to Professor Emil Kütter, professor of surgery at Marburg, honorary member of the German Society of Surgery, author of numerous surgical works, and a pioneer of antisepsis in Germany, on the occasion of his 90th birthday.

A REVISED list of English-speaking medical practitioners in various towns on the continent of Europe and in Northern Africa has been compiled by the Continental Anglo-American Medical Society, and may be obtained, free of charge, upon application to the secretary of the society, Dr. B. Sherwood-Dunn, 54, Boulevard Victor-Hugo, Nice.

THE Professional Classes Aid Council was formed during the war, and the British Medical Association is officially represented on it by Mr. Bishop Harman. The council's report for the year 1928-29 again emphasizes the council's ... records especially the ... children whose parents ... of students, grants in illness, and gifts of clothes are provided, and an advisory branch is of great value in directing applicants into the right channels for obtaining help. The utmost care is taken in co-operating amicably with other societies. The finances are satisfactory, but subscriptions remain very small in proportion to donations.

DURING her recent visit to Washington, Madame Curie received from President Hoover the sum of 50,000 dollars, which had been collected by American women to buy one gram of radium in Belgium for the Curie Cancer Hospital in Warsaw.

DR. A. G. WHITAKER'S retirement from practice at Evershot, after twenty-two years, was made the opportunity of presenting him with a cheque for £458 from five hundred subscribers as a mark of their esteem. In the absence of Dr. Whitaker through ill health Lady Ilchester handed the cheque to Mrs. Whitaker.

DR. T. N. KELYNACK, after nearly twenty-eight years' service as a physician on the acting staff of the Mount Vernon Hospital, has been appointed a consulting physician, an honorary life governor, and a member of the council of management of the hospital.

PROFESSOR HUGO SPITZY of Vienna has been made a corresponding member of the American Orthopaedic Association; Professor E. Hoffmann, director of the Skin Clinic at Bonn University, has been made an honorary member of the Japanese Society of Syphilology; and Professor Louis Pousep, director of the Neurological Clinic at Tartu, has been nominated Doctor honoris causa of the Stephen Bartorii University of Vilna, and corresponding member of the Portuguese Academy of Sciences and the Brazilian Society of Neurology and Psychiatry.

THE following appointments have recently been made in foreign faculties of medicine: Professor Walther Frey, director of the medical department of the Catherine Hospital at Stuttgart, as successor to Professor Sahli in the chair of internal medicine at Berne; Dr. Emil Gotschlich, professor of hygiene and microbiology at Heidelberg; Dr. Broemser of Basle, professor of physiology at Heidelberg; Dr. Maurice Favreau, professor of clinical obstetrics at Lille; and Dr. Ernest Gellhorn, professor of physiology at Halle, associate professor of physiology in the department of animal biology of the State University of Oregon.

DURING the year 1927-28 the German people spent 4,058,000,000 marks on beverage alcohol, or 74 marks per head, of which 43 marks were spent on beer, 13 marks on brandy, and 8 marks on wine. The increase in expenditure for 1928 on alcohol over that for 1927 was 358,000,000 marks.

WE regret to learn, at the moment of going to press, of the sudden death, on November 27th, of Lieut.-General Sir Arthur Sloggett, K.C.B., K.C.M.G., K.C.V.O., who was Director-General of Medical Services, British Armies in the Field, from September, 1914, to June, 1918. We hope to publish an obituary notice in next week's issue.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscia Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

STIMULATION OF BREAST SECRETION.

DR. L. L. STELLE (Blyth) writes: I have a patient who is very anxious to feed her baby, aged 1 month, at the breast, but the milk is slowly diminishing. She has had lactagol, a generous diet, including groats, a liberal supply of milk, and stout. Perhaps some of your readers know of a more efficacious method of increasing the supply of milk; I should be very grateful for information.

DENTAL ANAESTHESIA FOR CHILDREN.

"W. D." asks for advice as to the best anaesthetic to give to children and young people for extracting teeth. He writes: Ether, I know, is the safest, but unpleasant; using ethyl chloride first they almost come round at commencement of the ether sequence. Even mitigated chloroform I have been taught is dangerous. Open ether takes so long to get them under (which dentists resent); a Clover smallest face-piece is too large, and, also, the apparatus frightens them.

INCOME TAX.

Contributions to Superannuation Fund.

"DEPUTY M.O.H." is in the public health service and is contributing to the superannua[illegible] proceeding to a new appointment, and [illegible] paid back to him. Are these refunded [illegible] charged to income tax?

*** Our correspondent does not specify the Act of Parliament under which his contributions have been required, but no doubt he will find that his case will follow the course normal in such circumstances—that is, he will *not* be regarded as liable to be charged to income tax, but when the refunded contributions are paid to him there will be deducted the amount of tax of which he was relieved by reason of the payments of his contributions—which, after all, seems fair enough, as, in effect, those payments will now be cancelled by the refund to be made.

Allowances to Sister-in-Law.

"B. F. J." finds it desirable to make his sister-in-law an allowance of £25 a year. Can he do so in such a way as to avoid paying income tax on that amount?

*** Yes, provided that he places on himself the *legal* obligation of making the payment; in such circumstances the £25 a year will become the income of his sister-in-law and not of himself. The best method is to execute a deed binding himself to pay £25 a year—for example, in quarterly sums—during the joint lives of his sister-in-law and himself, or for a period of seven years, whichever be the less. It is essential that he should not retain a power of revocation, and that the legal obligation should not terminate after a shorter period than their joint lives or six years. No doubt the phraseology of the deeds in use by charitable bodies will assist him in drafting the necessary deed.

LETTERS, NOTES, ETC.

ROSS AWARD FUND.

SIR JAMES BAIR, chairman of the Ross Award Fund Committee, writes: Those of your readers who have subscribed to this fund will be interested to hear that the officer commanding the 1st Battalion, the Sikh Regiment, at Razmak, Waziristan, has sent a cheque for £15, the amount having been chiefly subscribed by the men of that battalion, who willingly gave it from their pay. The O.C. explains that this fund is of particular interest to the battalion because not only did Sir Ronald's father, General Sir Campbell Ross, command the battalion as Colonel (it was known as the 14th Sikhs, when Sir Ronald was born in India), but also Sir Ronald's brother, Captain C. Ross, was killed while serving with this battalion during the Chitral campaign. Your readers will be further interested to know that the fund has now reached £10,619 3s. 7d., of which the *Straits Times*, Singapore, has contributed £3,362 19s. 10d. and the *Malayan Daily Express* Fund £75 15s. 4d. Donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15.

TUBERCULOSIS MORTALITY.

DR. W. CAMAC WILKINSON (London, W.) writes: In a lecture at Edinburgh on November 6th, so says your *Journal*, November 23rd (p. 978), Dr. Harley Williams is credited with saying: "In Scotland at the present day no fewer than one person out of every three between the critical ages of 15 and 25 died from tuberculosis." If this be true there is no hope of realizing in Scotland the later statement that "during the lifetime of many present-day persons tuberculosis would be reduced to negligible proportions." The wish is merely father to the thought.

MOTORIST'S HEEL.

MR. A. P. BERTWISTLE, F.R.C.S.Ed., writes: I am sorry to have missed "G. F. P.'s" reply on this subject (November 23rd, p. 992); his personal description fits in exactly with mine. I feel sure, however, that the pain is fascial in character because it comes on the morning after the run, and is most marked at the origin of the plantar fascia. It is similar in the former respect to the stiffness of the neck which develops the day after sitting in a draught, or that after unaccustomed exercise; both start the morning following. I consider "*Notes and Queries*" a most useful feature of the *Journal*. True, one sometimes draws a blank, but often one gets most interesting personal replies.

ASTHMA TREATED BY COUNTER-IRRITATION.

DR. W. J. MIDDLTON (Bournemouth) writes to say that he has for many years treated asthma by means of continuous counter-irritation, with gratifying results. Since there is no concensus of opinion as to the etiology of asthma, he holds that any remedy which gives practical results is well worthy of consideration. He has no doubt that in a large percentage of the cases there is an underlying tuberculous element. His procedure is to make "a few dots by means of the galvano-cautery near the cervical enlargement of the spinal cord," or to employ multiple superficial acupuncture near the spinal column, followed by the application of a croton oil and cantharides mixture over the punctures.

SALT DEPLETION BY SWEATING.

DR. E. LUDOWICI, F.C.S.A. (Sydney, Australia), writes: The remarks on salt depletion by sweating, in the *Journal* of September 7th (p. 469), confirm the *view of men engaged* in bush work in Australia—that arduous [illegible] a diet of salt beef or mutton than [illegible] reputed to cause griping, so that [illegible] staple drink. [illegible] avoid plain wate[illegible] not have a gripi[illegible] and extractives,

A MISSING WORD.

OUR attention has been called to the unfinished state of the review published under the heading "*Health of British Troops in India*," in the *Journal* of November 16th (p. 910). It is obvious that something is missing at the end. This consists of only one word, and those who have wondered how many antimio[illegible] *tutes there are* in India will be interested to know that the missing word is "four." It apparently got lost on its way to press, for it was in its place in earlier proofs.

DR. W. EDWARDS (Norbury, S.W.) writes to say that the apparatus [illegible] examins, described by him on October 25th [illegible] the market by Messrs. S. Maw, Son, and [illegible] Street, E.C.

WE have received a reprint from the *Sydney University Medical Journal* for 1928 of an article by Dr. W. Stewart McKay on the anatomy and poison of the *dog tick* (*Ixodes holocyclus*), based on an experience with his own dog, in which suitable treatment was followed by recovery.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, 49, 50, 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement at page 243.*

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

479. Nervous Complications of Whooping-cough.

W. G. SEARS (*Brit. Journ. Child. Dis.*, July–September, 1929, p. 178), who records three illustrative cases in children aged 11 months, 3 years, and 5¼ years respectively, adopts the following classification of the nervous complications of whooping-cough: (1) convulsions or spasm of the glottis; (2) paralysis, which may be of the cerebral type and motor or sensory, or of the spinal type, spastic or flaccid; (3) meningeal syndrome and meningo-encephalitis; (4) peripheral neuritis; (5) mental and other nervous changes, including hysteria, hypochondria, melancholia, epilepsy, and dementia. The prognosis of all cases of pertussis with nervous complications is grave; a large number of those with convulsions associated with broncho-pneumonia are fatal, as is usually spasm of the glottis. In Valentine's series of 64 cases of paralysis in whooping-cough death ensued in 14, in 22 there was permanent damage, and in 28 recovery was complete. Of the paralyses which persist some remain flaccid, others become spastic or give rise to contractures, and athetoid or choreiform movements may arise in the affected limbs. Sears concludes that the primary cause in all the types of nervous complications in whooping-cough is a toxic one, and that a meningo-encephalitis is the primary lesion. Of his three cases the first was a male infant, aged 3 months, who developed right hemiplegia in the third week; the other two were a girl and a boy, aged 3 and 5 years respectively, with
developed within t
was eventually complete in an.

480. Pneumonic Infiltrations in Measles.

SUCCESSIVE skiagrams of the chest were taken of 130 children aged from 7 months to 12 years admitted to the Willard Parker Hospital, New York, with measles, and J. L. KOHN and H. KOIRANSKY (*Amer. Jour. Dis. Child.*, August, 1929, p. 258) report that pneumonic infiltrations, which were present in 62.4 per cent. of the children under the age of 4, and in 42.2 per cent. of those of 4 years old and over, were seen for the first time in the skiagrams in the pre-eruptive, eruptive, and post-eruptive stages. The infiltrations were of three types: (1) large homogeneous triangles; (2) large homogeneous opacities obscuring the hilar and paravertebral regions; and (3) disseminated confluent fine and coarse mottling in various areas of the lung field. A common site for the disseminated type was the cardiophrenic angles. The most frequent site of infiltration was the right lower lobe, and then, in order of frequency, the right upper, the left lower, and the right upper and right middle lobes. In most cases the infiltration was most dense as the rash was fading or in the post-eruptive stage; 79.2 per cent. of the cases in which no infiltrations were observed were clinically mild, as compared with 44.4 per cent. of those with pulmonary infiltrations. Of those patients who showed no pulmonary infiltration in the skiagram, 14 per cent. gave physical signs of bronchial or pulmonary involvement, as compared with 47 per cent. of the pneumonic group. The pneumonic shadows persisted for from two to four weeks after their first appearance. Abnormal intensity of the pulmonary markings was present in 80 per cent.; these were usually most intense during the height of the eruption. In 26.2 per cent. of all cases there was an interlobar shadow, which was seen only during the later stages of the disease, between the right upper and lower lobes of the lung. In 74 per cent. of all the cases there was a large and dense hilar shadow, which in 35 cases progressed and retrogressed while under observation. In 20 per cent. of the cases nothing abnormal was observed in the skiagram.

481. Primary Cutaneous Gonorrhoeal Infection.

V. GENNER and P. SCHULTZER (*Ann. de Derm. et de Syph.*, August, 1929, p. 856) report the case of a medical practitioner who, while retracting a gonorrhoeal prepuce, was slightly scratched by the patient's thumb; the hand was washed in soap and alcohol. Thirty hours later there was slight lymphangitis along the arm, followed by a small infiltration on the thumb, which on being incised two days later, gave vent to some serum. As the lymphangitis spread larger incisions were made, and some pus was found containing intracellular diplococci resembling gonococci. Later on severe articular pains set in affecting the shoulder; these were followed by involvement of the knees and considerable fever. Examination of the blood for the complement deviation test confirmed the existence of a gonococcal infection. As soon as the active joint symptoms ceased massage was used, and in spite of a long illness (from October to February) full use of the joints was recovered. There was never any suspicion that the disease was a septicaemia properly so called. The joint affections were typically blennorrhagic in character, being monarticular at the onset, spreading secondarily to other joints, muscles, and bursae, and finishing as a resistant sero-fibrinous arthritis of the knees.

482. Etiology of Striae Cutis Distensae.

F. LASCH (*Derm. Woch.*, July 6th, 1929, p. 978) reviews the literature, including the case reported by J. D. Rolleston (see *Epitome*, December 17th, 1927, para. 564), and records a case in a woman, aged 26, the subject of disseminated sclerosis; eight weeks after treatment with typhoid vaccine about six typical bluish-red stripes, measuring 5 cm. long and 1/2 cm. broad, appeared on each buttock. Since mechanical causes and disturbance of internal secretion could be excluded, the occurrence of the striae was attributed to the toxic action of the typhoid vaccine on the elastic tissue of the skin, as in the case of typhoid fever, which is one of the most frequent causes of striae cutis distensae and of the localized form, striae patellares. The time of appearance of the striae after the injection of typhoid vaccine also corresponded with the date of their appearance after typhoid—namely, forty-three days (Rolleston), three months (Benartowicz), and eleven weeks (Strasser).

483. Rheumatism with a Prostatic Focus.

PAZOS DE DIEGO (*La med. Ibera*, September 7th, 1929, p. 242), after quoting the statement of Tapia and Marañón that the conception of focal rheumatism is perhaps the most important idea introduced into the pathology of rheumatism of recent years, records two cases in men, aged 48 and 44 respectively, who had had rheumatism for many years. On examination they were found to be suffering from chronic prostatitis. Rapid disappearance of the rheumatism ensued after the prostatitis had been successfully treated by massage and irrigation.

Surgery.

484. Lung Abscess.

F. R. HERRIMAN and F. WELKER (*Med. Journ. and Record*, October 2nd, 1929, p. 361) advocate the treatment of lung abscess by aspiration and cleansing of the cavity, the bronchoscope affording a safe and generally efficient means of establishing drainage. They consider that surgery should be employed only in those cases in which bronchoscopic treatment has been tried and failed, and that when it is found necessary there should be the fullest co-operation between the internist, roentgenologist, pathologist, bronchoscopist, and surgeon. An hour before the operation an injection of morphine and atropine is given; under local anaesthesia the tube of the bronchoscope is passed, and any bleeding is controlled by the application of adrenaline solution. The tube is inserted into the bronchus of the suspected lung and a search is made for the tributary draining the abscess cavity; a cannula is introduced into this, and the pus is evacuated by suction. The cavity is then washed out with normal saline solution, and one or two drachms of a 25 per cent. argyrol solution are instilled. In long-standing conditions several such treatments may be necessary to effect any substantial improvement, but a gain in the patient's general condition is often noted soon after the first of these. In the experience of the authors the procedure is well borne and successful; contraindications for its use include fulminating suppurative pulmonitis, likelihood of the abscess rupturing into the pleural cavity, organic cardio-vascular disease with marked hypertension, recent severe pulmonary haemorrhage, intercurrent tracheo-bronchitis, and the presence of multiple abscesses.

485. Cholesterosis of the Gall-bladder.

C. F. W. ILLINGWORTH (*Brit. Journ. Surg.*, October, 1929, p. 203) describes two types of cholesterosis, the most common being the "strawberry" change in which the infiltration is widespread, and the rarer type in which localized deposits of cholesterol occur in small polypoidal projections of mucous membrane, "cholesterol polypi"; the two types are often associated. In the first the mucous membrane of the gall-bladder is congested and deep red, with innumerable tiny specks of yellow. The epithelium and stroma of the mucous

membrane is also infiltrated with lipoids and especially with cholesterol; in the stroma a characteristic feature is the presence of large foamy cells of endothelial origin. Cholesterosis is a condition chiefly of middle life, and is usually associated with cholecystitis and gall-stones. The symptoms are very varied, the majority of cases giving no indication that there is cholesterosis present, since the local signs are merely those of chronic cholecystitis. The cholesterol content of the blood is raised in some cases. Cholecystography, which indicates the presence of gross chronic cholecystitis or of stones, is of value in the diagnosis. Treatment by cholecystectomy gives good results, and six patients with uncomplicated cholesterosis who were so treated remained free from any recurrence of the severe symptoms from which they were suffering before operation. Experiments indicate that cholesterosis is brought about by a prolonged state of hypercholesterolaemia associated with a mild chronic bacterial cholecystitis. It results from two essential primary changes: an increase in the cholesterol content of the bile which leads to the absorption of cholesterol into the mucous membrane of the gall-bladder; and, secondly, a change in the physical and chemical state of the absorbed but invisible cholesterol which renders it optically active and recognizable, and which, by preventing its transport, leads to its accumulation in the wall of the gall-bladder.

486. Dysinsulinism due to a Pancreatic Tumour.

G. HOWLAND, W. R. CAMPBELL, E. J. MALTBY, and W. L. ROBINSON (*Journ. Amer. Med. Assoc.*, August 31st, 1929, p. 674) report a case which, from the history of convulsions and coma, the hypoglycaemia, and the cure of the condition, they feel justified in considering to be one of dysinsulinism. A married woman, aged 52, had for six years suffered from attacks of coma and convulsions, which increased in frequency; they could generally be warded off by the administration of food, and were found to be due to low blood sugar levels. While the patient was in hospital there was an erratic response to carbohydrate administration. Frequent attacks of convulsions and coma were the outstanding features, and suggested a neurological disorder. They actually proved to be a somewhat unusual manifestation of an excessive liberation of insulin resulting in a hypoglycaemia, and a pancreatic tumour measuring 1.5 cm. in diameter was removed. Histological examination showed that it was a carcinoma of the islets of Langerhans; insulin was recovered from the tumour mass. No metastases were found. During the fourteen weeks following the operation there was no clinical evidence, subjective or objective, of the recurrence of the attacks in any form.

487. Technique in Cholecystectomy.

F. H. LAHEY (*New England Journ. of Med.*, September 12th, 1929, p. 522) stresses the importance in cholecystectomy of the careful dissection of the cystic duct for its thorough exposure throughout its entire length. He asserts that the most common cause of stricture of the main bile ducts is operative trauma at two points—one in the hepatic duct where the cystic artery crosses it at its origin from the hepatic artery, and the other where the cystic duct joins the common duct. In order that an adequate mobilization and demonstration of the junction of the cystic, common, and hepatic ducts may be made possible, the author advises tying and dividing the cystic artery in all cases after carefully separating it from the cystic duct. The reason for such a procedure is that, the artery being considerably shorter than the duct, its preliminary ligation and division allows a much freer field for the exposure of the hepatic and common ducts, and of the angle between the hepatic and cystic ducts. Without such ligation there is the danger of the artery being torn when upward traction is made, owing to the fact that, the artery being the shorter, all the strain of upward traction upon the duct comes upon it rather than upon the duct. The procedure also makes the demonstration of a small stone at the junction of the cystic and hepatic and common ducts easier, prevents injury to the hepatic artery, and permits accurate clamping of the cystic duct at the proper distance from the common and hepatic ducts.

488. The Surgical Treatment of Diabetes.

M. DONATI (*Arch. Ital. di Chir.*, July, 1929, p. 357) records a case of diabetes treated by excision of the nerve supply to the left suprarenal gland. A woman, aged 54, had suffered from diabetes for seven months; there was 22 per cent. of sugar in the urine and 2·85 per cent. glycaemia. Under insulin (80 units per diem) the glycosuria disappeared and the glycaemia dropped to 1.8 per cent. An injection of insulin was given on May 16th, and on the following day the left suprarenal was exposed; the nerves were resected and their ends touched with 4 per cent. carbolic acid. After the operation the patient was given the ordinary hospital diet including carbohydrates, when the glycaemia rose to 2.1 per cent. and the glycosuria to 18 per cent. From May 31st to June 12th progressively diminishing doses of insulin were given, and from June 12th to the present time its administration ceased. Donati reports that in spite of a diet rich in carbohydrates, there is now no glycosuria and the glycaemia is 1.2 per cent. The amount of urine passed daily has decreased from 1,350 c.cm. before the operation to 450 c.cm., and the thirst and other functional symptoms have disappeared.

Therapeutics.

489. Treatment of Exophthalmic Goitre.

REVIEWING the various methods employed in the treatment of exophthalmic goitre, P. SAINTON (*Journ. de Méd. et de Chir.*, October 10th, 1929, p. 685) points out that the syndrome of this disease is a neuro-endocrine complex in which probably a hyper- or dys-secretion, or at least a paradoxical hypersecretion of the gland and changes in the vago-sympathetic system occur. Treatment is purely symptomatic, and is of two types—that of the nervous and that of the thyroid element. Each case demands individual study, based on the following considerations: examination of the gland as to its volume, form, and consistency; manifestations of a neurovascular order—exophthalmia, tachycardia, and vasomotor and psychic troubles; the effect of the disease on metabolism, especially the basal metabolism; and the conditions synchronizing with the appearance of the syndrome—namely, the duration of the goitre, heredity, puberty, and the menopause. The disease can then be diagnosed as true primary exophthalmic goitre, adenomatous goitre, or as an infectious, congestive, endocrine, or merely a reflex reaction. The nervous treatment is general (of the psychic state), or local (of the sympathetic system). General measures include absolute physical and mental rest, with which various forms of hydrotherapy may well be combined. Sedatives such as valerian and the bromides are also useful. Vago-sympathetic treatment may be medical, surgical, or physical. Among the medicaments are the quinine salts and ergotamine tartrate. Surgical measures employed are resection of the cervical sympathetic and of the stellate ganglion. Various forms of electrical treatment have given good results if combined with radiotherapy. Treatment directed to the gland itself consists of iodized medication, injections of the blood of thyroidectomized animals, radiotherapy, and operation. Iodotherapy is an excellent pre-operative measure; as a curative agent its use requires careful watching. Haematoethyroidin, prepared from the blood of thyroidectomized animals, has been found of value in slight or moderate cases. Though not favoured by surgeons, radiotherapy has given brilliant results in true exophthalmic goitre. The author believes that any surgical intervention should be early, and be attempted only when the basal metabolism shows an increase of over 20 per cent. Certain adjuvant remedies, such as opotherapy and insulin, have been found beneficial. Crile's hypothesis that other factors (endocrine or nervous) than the thyroid are concerned in the pathogeny of the disease is cited. Sainton suggests as a cause a diathesis which consists of a combination of a congenital nervous factor and a tendency to goitre.

490. Serum Treatment in Type I Lobar Pneumonia.

SINCE experimental studies indicated that the serum of horses, highly immunized to Type I pneumococci and administered in very large doses, should produce favourable results in pneumonia due to this micro-organism, R. COLE (*Journ. Amer. Med. Assoc.*, September 7th, 1929, p. 741) instituted, with his associates, this form of treatment at the Hospital of the Rockefeller Institute. Type II serum was also tested in a few cases, but experimental and clinical observations soon showed that serum treatment in pneumonia, if successful at all, was most likely to be efficacious in Type I cases. Treatment was commenced in 1913, and of 1,256 cases of lobar pneumonia, 431 were definitely determined as due to Type I pneumococci. Of these, 44 patients died, a mortality rate of 10.2 per cent. If 69 cases with 5 deaths in which the serum was not administered are omitted, the corrected figures become 371 patients who received the serum, 37 deaths, and a mortality rate of 10.5 per cent. This low mortality was not due to slight severity of the disease or to early hospitalization. Positive blood cultures in 32 per cent. showed that the cases were at least of average severity, and the date of admission to hospital in 30 per cent. of the cases was the fourth day of the disease or later. The average time of commencing treatment was 4.2 days after onset in the patients who recovered, and 5.2 days in the fatal cases. Early treatment cannot be the sole factor in the favourable results, and Cole regards as equally important the use of good serum of a high titre in large amounts, and constant supervision of the patient.

Repeated doses of 100 c.cm. were administered; the average amount used per patient was 420 c.cm., though many received much more than this. If necessary, attention was paid to the patients for the whole twenty-four hours of the day, so that no delay might occur in determining the type of infecting organism and in promptly administering the serum. The fatal cases are reviewed, and a study of these indicates that no other form of specific treatment would have been of greater value. Cole admits that the present method of treatment with large doses of serum is not ideal. However, it is doubtful whether small doses of concentrated serum have any effect on the mortality. Unless large doses of the latter are employed, or a more accurate method of standardization is adopted, it is better, he thinks, to continue to treat cases of Type I pneumonia with large doses of a good variety of whole serum.

491. A Modified Protein-Shock Therapy.

GÉRARD (*Bruxelles-Méd.*, October 6th, 1929, p. 1402) records his experience of treating certain skin diseases by the intramuscular injection of a milk preparation incorporating hexamethylene tetramine and termed lacrénile. The initial dose was 5 c.cm., going up to 10 c.cm. at intervals of two or three days. Beyond the usual sequels of such injections no ill effects followed. The best results were obtained in the chronic and resistant forms of urticaria, psoriasis, and chronic eczema. The author gives brief notes of cases treated by this method, and comments on the value of associating protein shock with a form of chemotherapy directed against infective conditions. The milk is employed in the form of whey, which results in a less violent reaction than when whole milk is injected. The reaction is, however, not so feeble as that of autohaemotherapy, which is less effective in these chronic conditions.

Neurology and Psychology.

492. Subacute Combined Degeneration of the Cord.

BASED on an analysis of 61 cases, 30 of which were treated with liver since January, 1925, C. C. UNGLEY and M. M. SUZMAN (*Brain*, September, 1929, p. 271) describe the symptomatology of subacute combined degeneration of the cord and the effects of liver therapy in that disease. In every case there were definite signs of involvement of either the posterior or lateral columns of the cord, or of both. Incoordination and ataxia from loss of muscle and joint sensibility and loss of vibration sensibility were regarded as evidence of posterior column involvement; Babinski's sign, with or without exaggeration of the deep reflexes and patellar or ankle clonus, was taken as evidence of degeneration of the lateral pyramidal fibres. The sexes were involved almost equally, and the ages of the patients ranged from 29 to 65. Cases in which heredity seemingly played a part have been recorded in the literature. As a rule, the patients have been singularly free from previous illnesses, and the onset was usually insidious. A sudden onset (present in only 3 cases) was not necessarily associated with a rapid subsequent course. In 39 cases the first symptoms were referable to the nervous system, in 10 to the alimentary tract, and in 12 to anaemia. Symptoms of the established disease are enumerated under the same headings. The nervous signs noted were: numbness and tingling in the extremities, girdle sensation and pains in the back and limbs, and other dysaesthesias. A common complaint was that objects felt cold to the skin; insensibility to touch and pin-prick was commonly present. Inco-ordination and ataxia of the lower limbs was noted in all cases in which these signs could be elicited; vibration sense in the tibiae and joint sense in the big toes were absent or impaired whenever noted. Astereognosis occurred in 8 cases, and athetoid movements in one. Ocular manifestations appeared in several instances, but mental disturbances in only 3. Disturbances of micturition were noted in 26 cases, and in all except two of these other indications of pyramidal involvement were present. Signs of involvement of the alimentary tract, such as unsound teeth, Hunterian glossitis, and gastro-intestinal symptoms and achlorhydria, were invariably found. Every patient, except 6, exhibited a definite degree of anaemia with a very low red cell count; the colour index was usually above unity, and the blood films were sufficiently typical of pernicious anaemia to be of great diagnostic value. Yellow discoloration of the skin was present in all cases with marked anaemia. The benefits of liver treatment are clearly shown in the two series of patients. In the 30 treated with liver, 17 improved, 8 were not improved or became worse, and 5 died; in the 31 not so treated, none improved, 3 were not improved or became worse, and 28 died. The best results were obtained by an intensive course (3½ to 4 lb. of liver a week) for six to eight weeks, followed by 1½ to 2 lb. weekly indefinitely. It is stated that liver extract may be substituted if necessary. The authors consider that the beneficial effect of liver on the nervous system is a specific phenomenon, and not the result of the maintenance of the red cell count at a high level, or of improvement in the general condition. The disease is probably a deficiency one occurring in persons with a certain constitutional diathesis, and, since all the signs of cord involvement may disappear, it would seem that the degenerative changes in the white matter in this disease are not necessarily of a permanent character.

493. Optic Changes in Epidemic Encephalitis.

S. ROTHENBERG (*Journ. Nerv. and Mental Dis.*, September, 1929, p. 271) remarks that epidemic encephalitis is unique as regards its widely varying syndromes, of which several kinds have been observed in different localities; thus, for example, mental symptoms predominated in the early cases of the New York epidemic of 1923. A series of nine cases of acute epidemic encephalitis is now reported, in which changes in the optic fundus, such as neuritis, choked disc, optic atrophy, or sudden amaurosis predominated over all the other symptoms. Lethargy and diplopia were transient symptoms in a few instances, while signs of organic affection, other than the fundal changes, when present, seemed subordinate to these symptoms, and developed subsequently to the eye findings. In three patients the ocular signs were associated with decided psychoses, with marked agitation and restlessness, symptoms which were probably due to the same encephalitic infection involving the cerebral frontal lobes. Spinal encephalography was performed in three cases, with one fatality; in the two remaining cases the *x*-ray pictures showed the ventricles to be normal in character and outline. Another unusual feature noted in this series was the finding of a low sugar content in the spinal fluid in more than one-half of the cases. The "follow-up" review of the patients revealed no symptoms or signs indicative of slowly growing brain neoplasm; with one exception, all made a progressive recovery, though in some the optic neuritis and atrophy have remained permanent. A similarity was noted in the mental disturbances of the three cases, all the patients manifesting marked disorientation, psychomotor overactivity, euphoria, and, at times, delusions. Two of these patients recovered completely, except for the eye changes. Rothenberg adds that the differential diagnosis between encephalitis and brain tumour is always difficult; often only the history of sudden onset with severe headache, raised temperature, the spinal fluid pleocytosis, and the subsequent clinical course of the disease can be relied on to distinguish encephalitis from cerebral neoplasm.

494. Centrolobar Cerebral Sclerosis.

J. MARIE (*Ann. de Méd.*, July, 1929, p. 162) gives a clinical study of subacute centrolobar cerebral sclerosis—diffuse peri-axial encephalitis, or the malady of Schilder-Foix—having in a previous communication in the same journal (December, 1928) described its pathological anatomy. This affection is not peculiar to infancy, as formerly seemed the case, its maximum incidence being between the 20th and 30th years. The type generally encountered simulates the symptomatology of cerebral tumours. The onset is usually not abrupt; it is characterized by the progressive development of a neurological syndrome of visual, motor, and psychic disturbances, each of these predominating in different cases. Among the first-named group are diminution of vision, hemianopsia, dyschromatopsia, and congestion of the fundus of the eye. Motor troubles comprise spastic mono-, hemi-, or quadriparesis, with or without aphasia; and the psychic, inertia, apathy, and slowness of ideation. Three or four months after its onset the disease becomes established, and blindness usually supervenes. The motor disorders increase in intensity, and are remarkable not so much for the paralysis as for the intense degree of the contractures. Convulsive crises of painful, spastic, paroxysmal cramps may appear. The psychic troubles are the most marked, and consist essentially of a progressive failing of the intellectual faculties. Accessory symptoms are disorders of speech, and sensorial, sensory, and ataxic disturbances. Examination of the fundus of the eye may be a decisive diagnostic factor; in 50 per cent. of the cases a moderate papillary stasis is noted. As the disease progresses the extreme intensity of the contractures increases and a definite tetaniform rigidity supervenes. The patients more or less rapidly fall into a state of profound dementia, with rectal and vesical incontinence and cachexia; death ensues twelve to eighteen months after the onset. The malady is not necessarily fatal, and may assume a chronic form. The diagnosis is extremely difficult, and the disease must be distinguished from cerebral tumours, subacute sclerosis en plaques, optic neuro-myelitis, epidemic encephalitis, and cerebral syphilis. Four theories have been advanced as to pathogeny: neoplasmic, degenerative, infectious, and toxic. Marie, agreeing with Foix, believes that the disease is an infection due to an unknown virus. Twenty cases are described, some in considerable detail,

Obstetrics and Gynaecology.

195. Use of Lipiodol in Gynaecological Diagnosis.

DOUAY (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, July, 1929, p. 447) points out that the employment of lipiodol in cases of carcinoma of the uterine body is not without danger. Small fragments of malignant tissue may be carried into the tubes and even into the peritoneal cavity. He advises, therefore, that the lipiodol should be injected at a low pressure while the patient is being screened, and that as soon as the required picture presents a plate should be taken. Even with this careful technique the oil sometimes passes into the tubes, but the likelihood of peritoneal infection is not so great in the case of cancer of the uterine body as it is in cervical carcinoma, though there is definite risk of the malignant cells being carried into the peritoneal cavity. Therein lies the danger of this method. Douay, moreover, draws attention to the fact that, while fibroids under the endometrium and intrauterine polyps are shown up quite clearly and quite differently from a carcinoma, the latter may be simulated very largely by intrauterine blood clots. He considers curetting a superior diagnostic method, but there are cases where the uterine cavity may be distorted by a fibroid tumour, and where, as a result, the curette may miss the malignant area, or where the cervical canal may be occluded by tumour formation. In these cases examination by lipiodol may prove a useful adjunct in diagnosis.

196. F. BOTIN (*La med. Ibera*, September 28th, 1929, p. 301) reports his experience of the radiographic diagnosis of gynaecological conditions by intrauterine injections of lipiodol. The procedure appears to be quite safe; even pregnant women have unintentionally been injected with no ill effect. Botin states that it is impossible to prevent some of the liquid overflowing into the peritoneal cavity; but the slight pain which may occur some hours afterwards is due not to this but to the uterine and cervical manipulation; patients should rest for twenty-four hours subsequent to injection. The method can indicate stenotic lesions of the tubes which even at an operation might escape the eye. The normal radiograph shows the uterus as a triangular figure with its base above; all its sides are slightly convex but regular. The tubes appear as rather uneven lines; this is due to peristalsis and explains why their directions are not quite similar, but the lipiodol is not fragmented in normal tubes. At the angles of the uterus the tubes run perpendicularly to it; then their line dips down and passes outward to the abdominal ostium, where the lipiodol forms a pool. A uterus deformed by large fibroids appeared on the film with its cavity transverse; no tubes showed because the tumour had blocked their internal ostia by pressure. Another film showed a uterus in left retrolateral flexion, with a permeable left tube and an obstructed right one. In another case an ovarian cyst of uncertain location had been diagnosed on clinical grounds. The *x*-ray examination showed one tube with an abnormal direction; it seemed to surround an invisible mass placed above the uterus. Presumably the ovary had been fixed in an anterior plane by some inflammatory process on the back of the broad ligament, and the cyst had developed there. A fifth case showed permeability of the left with complete obstruction of the right tube by stenosis of its external ostium; the corresponding uterine horn had lost its sharp angle and was dilated. The author remarks that complete tubal obstruction produces this appearance. All these diagnoses were confirmed at subsequent operations.

197. The Sedimentation Test in Gynaecology.

HAVING used the sedimentation test for more than a year as a routine procedure in the case of every gynaecological patient admitted to hospital, H. H. JOHNSON and J. S. DIASIO (*Med. Journ. and Record*, September 18th, 1929, p. 316) report their conclusions based on 150 cases. The Friedländer modification of the Linzenmeier method was employed. Readings were taken every five minutes and the time was noted when the erythrocyte column reached the 18 mm. mark. Normally this is longer than two hours; sedimentation times of less than thirty minutes were held to indicate an acute infection, between thirty and sixty minutes a subacute infection, and over sixty minutes a chronic infection. The most rapid rates occurred in pelvic suppurations associated with fever and leucocytosis, six cases of pelvic abscess showing sedimentation times of between eleven to eighteen minutes, with the leucocyte count ranging from 26,300 to as low as 13,500. The speed of sedimentation was markedly increased with the elevation of the temperature and the leucocytosis. The authors conclude that the test is of value in determining the safe time for operation; it is thought also to be a more delicate prognostic index than the temperature curve or leucocyte count. Before its adoption operations were performed in accordance with Simpson's rule, the time chosen being when the temperature and leucocyte count had been normal for at least a fortnight; but operations upon cases which fulfilled these requirements often proved hazardous, or even fatal, when the sedimentation rate was less than thirty minutes. Tests made during convalescence showed the progress of the patient; judging from those who had to be readmitted with a recurrence of pelvic pain and fever, it was found to be unwise to discharge patients to their homes with a sedimentation time of less than sixty minutes.

Pathology.

498. The Origin of Antitoxins.

G. RAMON (*C. R. Soc. de Biologie*, October 25th, 1929, p. 287) discusses the various explanations that have been offered for the method of formation of antitoxins. The original hypothesis put forward by Buchner, that antitoxin represented a simple modification of the toxin, has been abandoned by most workers on account of the difficulty in reconciling certain observations with it. One of the most important of these is that, if an animal which has been inoculated with a given toxin is bled copiously, the antitoxic titre of the blood may rise without any fresh injection of toxin. Though this observation has been made independently by several workers, Ramon doubts it. His experience has been that, provided a sufficient length of time is allowed to elapse between the last injection of antigen and the first of the series of bleedings, the effect of the bleeding is always to lower the antitoxin titre of the blood. He has come to the conclusion that no production or increase in antitoxin can take place independently of the presence of the antigen. His general idea of the formation of antitoxin is as follows: the antigen, on gaining access to the body, undergoes dissociation of a variable degree, due probably to the action of cellular and humoral ferments; as the result of the interaction between the antigen and the body tissues an antitoxin complex results, the specificity of which depends on the persistence in the complex of a chemical nucleus derived from the antigen.

499. Pathological Lesions in Rheumatic Fever.

A. F. B. SHAW (*Arch. Dis. Child.*, August, 1929, p. 155) records the detailed pathological findings in a girl, aged 15, who died from rheumatic fever with chorea. Macroscopically there was rheumatic endocarditis of the mitral and aortic valves, with the characteristic vegetations, organizing pericarditis, and opaque white points in the wall of the left ventricle, which were proved histologically to be Aschoff nodes. The endocardium of the auricles, the left more than the right, was roughened by numerous raised opaque yellowish flecks and ridges. There were some yellowish opacities beneath the endothelium of the tricuspid valve and at the base of each cusp of the pulmonary valve. Microscopically the lesions were widely distributed over the heart, some of the larger blood vessels, the muscles serous membranes, and lymphoid tissue. The changes in th were gross appearance. was found side by side. In the acute phase the endothelium raised up and the whole thickness of the endocardium, down to the muscle, was infiltrated with fluid and cells; large Aschoff cells were arranged in rows along the swollen collagen fibres inside and outside the elastic lamina. There was no fibrin deposit on the surface of the unbroken endothelium. Resolution and healing took place by the disappearance of the exudative cells and the formation of young scar tissue covered by intact endothelium. The author quotes the work of Bayne-Jones, who demonstrated a vasculature in the valves of normal hearts. He considers that the degree of strain and the amount of vasculature are conjointly responsible for the fact that involves the valves in the following nitral, aortic. tricuspid, pulmonary. He further that valvulit s precedes endocarditis, vegetations probably not occurring till the valvulitis spreads to the line of closure of the valve, when the additional factor, stress, comes into play.

500. Lymphatic Gland Extracts and Typhoid Infection.

A. FONTANA (*Il Morgagni*, September 8th, 1929, p. 1931) has conducted experiments with a view to testing the value of lymph gland extract in typhoid fever. Experiments *in vitro* with various lymph gland extracts showed that no bactericidal action was exercised on the typhoid bacillus. Lymph gland extracts, however, seemed to inhibit bacterial growth slightly when added to culture media. Experiments with guinea-pigs led Fontana to the conclusion that intramuscular injections of lymph extract might protect against typhoid fever. A mixture of extracts and bacilli introduced into the peritoneal cavity always resulted in death. The injection of emulsions of lymph glands conferred immunization on resulting disease when what

During the... Sunless Months.

* *The Lancet* (30 April, 1927) refers to the "unfortunate dispensation" of Nature, that, just at the winter season, when the human being is deprived of ultra-violet light, many of his chief articles of food also decline in the content of Vitamin D for the same cause.

The animals and plants growing in these islands are also deprived of ultra-violet light in the winter and their value as food accordingly diminishes. The diminution is most marked in the case of cow's milk and its derivatives."

Therefore, especially in winter, advise

SUNSHINE GLAXO

Sunshine Glaxo is pure milk, fully humanised and with "Ostelin" vitamin D added under carefully controlled conditions, in a definite quantity which has been determined by more than 2 years' clinical trial.

A trial supply gladly sent on request to:

MEDICAL DEPT., GLAXO HOUSE, 56, OSNABURGH ST., LONDON, N.W.1.

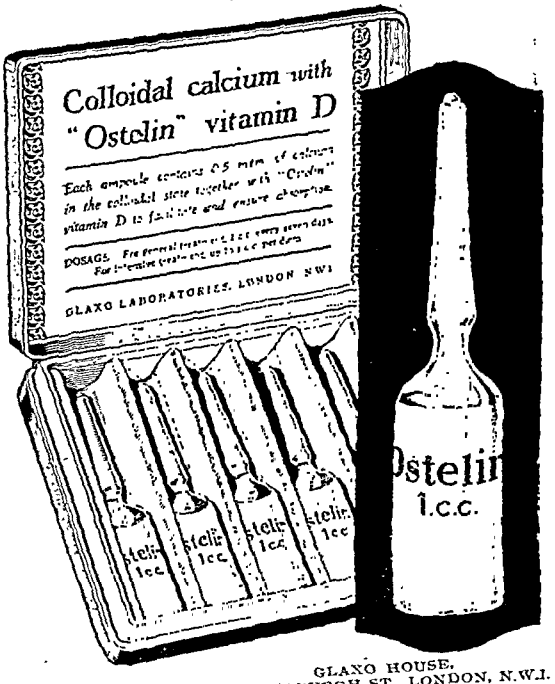
A NEW PREPARATION

Colloidal Calcium with Ostelin vitamin D

in ampoules for subcutaneous injection.

The presence of the Vitamin D in addition to the Calcium, besides giving a very pronounced tonic effect, rationalises the administration of Calcium and further prolongs the effect, as it facilitates the absorption and utilisation of Calcium from the bowel.

Clinical Indication. — In vasomotor skin affections, *chilblains*, chilblain circulation, urticaria, in gross nutritional failure occurring in debility diseases, and also in delayed union of fracture, these Ampoules have proved of value.



GLAXO HOUSE, 56, OSNABURGH ST., LONDON, N.W.1.

New Lines of Grace & Beauty

TRIUMPH
Super Seven

An entirely new radiator, safety glass, chromium plating, ten models, a wide range of colour schemes, hydraulic brakes—these are outstanding Triumph features.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, unconspicuous, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope especially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

"Baby immediately recommenced to thrive"

Testimonials to the value of Bovril for children are constantly reaching the Company. Read this remarkable tribute from Mr. David C. Healey, of 81, Harford Street, Middlesbrough:—"Try what we would nothing seemed to allay the failing condition of the baby until his mother decided to try the addition of a little Bovril to the milk." The result was striking and immediate. "From that day the baby recommenced to thrive both in health and temper, and peace was restored after an anxious and trying time."

CONVALESCENT HOME at BOURNEMOUTH standing in 9 acres of ornamental grounds, with tennis courts, etc., which Patients or Boarders may visit by arrangement, for long or short periods.

Illustrated Brochure on application to the Medical Superintendent, The Old Manor, Salisbury. Telephone 51.

PECKHAM HOUSE, 112, Peckham Road, London, S.E.15.

Telegrams: "Alleviated, London." Telephone: Rodney 4741—4742.

The above House, which was established in 1826, is an Institution for the care and treatment of persons suffering from mental diseases and nervous disorders. Both certified patients and voluntary boarders are received. Separate houses for treatment and accommodation of special cases adjoin the Institution. There is a seaside branch, Kearsney Court, near Dover, to which patients may be sent for treatment or on holiday. Motor and carriage exercise is provided as required. Patients can avail themselves of a course of physical drill. Tennis courts. Entertainments, dances, and indoor amusements held throughout the year.

Illustrated prospectus and further particulars can be obtained from the Medical Superintendent.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, *Plombières* treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are *cricket grounds, football and hockey grounds,* lawn tennis courts (grass and hard courts), *croquet grounds, golf courses, and bowling greens.* Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, *in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.*

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is *exclusively* for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

MAUDSLEY HOSPITAL,
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.
IN-PATIENTS: (*a*) 160 beds (both sexes) in wards or separate rooms. (*b*) 13 private rooms (*for ladies*) with special sitting rooms, garden, and dietary.

Terms:

(a) £5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.
(b) **£6 6s. a week.**

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. *Inquiries of* EDWARD MAPOTHER, M.D., M.R.C.P., F.R.C.S., *Medical Superintendent.*

[illegible] h further particulars [illegible] e obtained from the Ministry of Health,

[illegible] considered unless re- [illegible] form not later than December 7th, 1929.

Borough of Nuneaton.

ASSISTANT MEDICAL OFFICER.

The Council invite applications from male registered Medical Practitioners for the post of whole-time Assistant Medical Officer of Health and Assistant School Medical Officer under the direction, supervision, and control of the Medical Officer of Health, at a salary of £600 per annum, subject to deductions in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applicants must have had experience in the prescription of glasses for errors of refraction, ante-natal work, and children's ailments.

The appointment will be subject to three calendar months' notice on either side, and to the approval of the Ministry of Health and the Board of Education. The officer will be required to reside within the Borough of Nuneaton, and will not be allowed to engage in private practice.

The successful candidate will be required to pass a medical examination.

Applications, on forms to be obtained from the Medical Officer of Health, Health Department, Nuneaton, endorsed "Assistant Medical Officer of Health," accompanied by copies of three recent testimonials, must be delivered to the undersigned on or before December 14th.

Council Offices, Nuneaton. November 25th, 1929. W. H. POLLITT, Town Clerk.

The Radium Institute.

Riding House Street, London, W.1.

Applications are invited for the post of HOUSE SURGEON. Candidates must be fully qualified and unmarried, and the appointment is for a term of twelve months as from January 1st, 1930.

The salary will be at the rate of £150 per annum, with board, lodging, and laundry.

Applications, stating age, qualifications, and experience, with copies of three recent testimonials, must be received at the Institute not later than December 7th.

Canvassing, either directly or indirectly, is not permitted.

THOS. A. GARNER, Secretary.

Metropolitan Hospital,

Kingsland Road, London, E.8.

The Committee of Management are prepared to receive applications for the appointment of:

(*a*) An ASSISTANT SURGEON;
(*b*) Two ANÆSTHETISTS.

In the case of the first appointment, candidates must be Fellows of the Royal College of Surgeons of England and not engaged in general practice.

Candidates will be required to submit to Members of the Medical and Surgical Staff one copy of their application, with testimonials, and subsequently to call by appointment for interview. A list of the Medical and Surgical Staff and full particulars in relation to any of the appointments will be supplied upon request.

One copy of the application should be submitted as early as possible to the undersigned, but not later than first post on December 14th.

HERBERT F. RUTHERFORD,
Secretary & House Governor.

Western Australia.

Applications are invited from Medical Men for the position of JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER in the LUNACY DEPARTMENT of Western Australia.

Commencing salary £456 per annum, with annual increments of £24 up to £576. Salary to commence from date of taking up duty in Western Australia.

Transport allowance £200 for a married man, £100 for a single man.

Free furnished quarters, light, fuel, farm produce, with stores at contract rates for a married man. Furnished quarters and all found if appointee is single.

Should the successful applicant voluntarily relinquish the position before the expiration of two years from the date of his appointment, he will be called upon to refund the amount of the transport allowance.

Applications, which should be endorsed "Medical Appointment," must reach the Agent-General for Western Australia, Savoy House, 115/6, Strand, London, W.C.2, not later than December 17th.

Egyptian Government.

EGYPTIAN UNIVERSITY.

FACULTY OF MEDICINE.

Applications are invited for two posts as SURGICAL TUTORS.

The salary offered is £E.35 a month in Grade V, and the appointment will be on contract for one year, renewable at the end of that time. The appointment is to be a full-time post.

The candidates must be Egyptians, and preference will be given to those possessing the F.R.C.S. England.

Applications, accompanied by testimonials and references, should be addressed to the DEAN, Egyptian University, Faculty of Medicine, Cairo, so as to be received not later than December 15th, 1929.

Devonshire Hospital, Buxton,

DERBYSHIRE. (300 Beds.)
(A Special Hospital for Rheumatism and Allied Diseases.)

ASSISTANT HOUSE PHYSICIAN.

The Committee invite applications for this post. To commence duties December 23rd. The successful candidate will be engaged for a period of not less than six months. The appointment is not open to ladies. Salary commencing £150 per annum, rising to £175 after three months' service, with furnished apartments, board (excepting stimulants), and laundry. Applications, with copies of three recent testimonials, endorsed "Assistant House Physician," to be sent in at once. The Medical Staff consists of eight Honorary Physicians, an Honorary Surgeon, a Bacteriologist, a Radiologist, a Biochemist, and two Resident House Physicians. The Hospital contains a Pathological Laboratory, and X-ray Department. This appointment offers special facilities for anyone preparing a thesis or wishing to do research work.

Canvassing will disqualify.

By Order,
TOM B. HARRISON,
General Superintendent & Secretary.

Liverpool Stanley Hospital.

The Committee invite applications for the post of HONORARY PHYSICIAN to this Hospital. Full particulars may be had on application to the Hon. Secretary.

Applications, enclosing testimonials, addressed to the President of the General Committee, must be lodged with the undersigned at the Hospital on or before December 14th.

FRANK WHITE, Hon. Sec.

Liverpool Stanley Hospital.

Wanted immediately, One Male HOUSE SURGEON for period ending March 31st, 1930. Salary at the rate of £100 per annum, with board, laundry, etc.

Candidates must be on the *Medical Register*, and applications, with copies of three recent testimonials, should be lodged with the undersigned on or before December 7th.

E. W. OSBORN, Secretary.

Lowestoft and North Suffolk HOSPITAL, LOWESTOFT.

JUNIOR HOUSE SURGEON (male) required. Salary £120 per annum, with board, residence, and laundry. Applications, together with copies of three recent testimonials, to be sent to the Honorary Medical Superintendent.

Wilts County Council.

APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH and ASSISTANT SCHOOL MEDICAL INSPECTOR.

The Wilts County Council invite applications from Medical Men for the appointment of an Assistant County Medical Officer of Health and Assistant School Medical Inspector. Applicants must be fully qualified Medical Practitioners, and hold a Diploma in Public Health, or an equivalent qualification. Experience in Tuberculosis is essential, and preference will be given to candidates with experience in venereal diseases.

The salary will be £600 per annum, and will be subject to a deduction of 5 per cent. for superannuation under the Local Government and Other Officers Superannuation Act, 1922, and the candidate selected will be required to pass a medical examination. Travelling allowance for own motor car in accordance with County scale.

The officer appointed will be required to reside in or near Swindon, to devote his whole time to the duties of the office, and to act under the direction and control of the County Medical Officer of Health, who is also School Medical Officer. The duties of the post will be chiefly concerned with the School Medical Service, but the officer will be employed on other Public Health work. The appointment will be determinable by three months' notice on either side.

Applications, on forms to be obtained from the undersigned, together with copies of not more than three recent testimonials, and enclosed in envelope marked "Assistant Medical Officer," to be lodged with the undersigned not later than the first post on Friday, Dec. 6th.

Canvassing, either directly or indirectly, is strictly prohibited and will be regarded as a disqualification.

County Offices, Trowbridge. November, 1929. W. L. BOWN, Clerk of the County Council.

Surrey County Council.

PUBLIC HEALTH DEPARTMENT.

APPOINTMENT OF CHIEF CLERK.

The Surrey County Council invites applications for the post of Chief Clerk in the Public Health Department.

Candidates should possess a thorough knowledge of local government administration, preferably associated with a Public Health Department, and have had experience in controlling and directing a large clerical staff.

The salary will be £500 per annum, rising by annual increments of £20 to a maximum of £600 per annum.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be sent to the County Medical Officer of Health, 5, Grove Crescent, Kingston-on-Thames, Surrey, to whom any enquiries relating to the appointment should be addressed. All envelopes should be marked "Chief Clerk."

The last day for receipt of applications will be Saturday, December 7th.

Canvassing direct or indirect, will disqualify.

County Hall, Kingston-on-Thames. November 20th, 1929. DUDLEY AUCKLAND, Clerk of the County Council.

City of Leeds.

CHIEF ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from qualified and registered Medical Practitioners for the post of Chief Assistant Medical Officer of Health for the City of Leeds. Candidates must not be more than 40 years of age and, in addition to previous experience in Public Health administration, should also have had experience in one or more of the special branches of Preventive Medicine, e.g., School Medical work, Tuberculosis, Maternity and Child Welfare, etc.

The person selected will be required to devote his whole time to the office, and to perform such duties as are allotted to him by the Medical Officer of Health. It will be necessary for him to enter into an agreement of service with the Corporation terminable by three months' notice on each side and to pass a medical examination, and contribute to the Superannuation Fund established under the Local Government and Other Officers Superannuation Act, 1922.

The salary will be £900 per annum. Applications, stating age, qualifications, and experience, together with copies of three testimonials, to be addressed "Chief Assistant Medical Officer," to the undersigned at my office, 26, Great George Street, Leeds, not later than December 6th.

THOS THORNTON, Town Clerk.

Leeds

County of Hertford.

APPOINTMENT OF ASSISTANT LADY MEDICAL OFFICER OF HEALTH FOR MATERNITY AND CHILD WELFARE SERVICES.

The County Council of the Administrative County of Hertford invite applications for the above-mentioned appointment.

Applicants must not be more than 40 years of age. Salary £600 per annum. Actual and necessary travelling expenses will be provided.

Candidates must be fully qualified and registered, and should have had previous experience in Maternity and Child Welfare work, including modern methods of ante-natal care and supervision.

The work will be performed under the control of the County Medical Officer of Health.

The applicant appointed will be required to reside at such place in the County of Hertford as may be directed.

The person appointed will be required to commence her duties at an early date and to devote the whole of her time to the duties of the office. She will hold office during the pleasure of the County Council, and if she desires to leave their service must give them three months' notice of her desire so to do.

Applications should be sent to the undersigned not later than December 21st.

The applicant appointed will be required to sign an agreement containing the terms and duties of her appointment.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the County Council.

CHARLES E. LONGMORE, Clerk of the Peace Office, Hertford. November, 1929. Clerk of the Hertfordshire County Council.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM (333 Beds).

SENIOR ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Senior Assistant Medical Officer.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Applicants must have held resident hospital and sanatorium appointments, and have had practical experience in the diagnosis and modern methods of treatment of tuberculosis; practical experience in radiology is desirable.

Salary £500 per annum, with board, residence, and laundry in addition.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope, "Medical Officer, Baguley Sanatorium," must be addressed to the undersigned only, and not to members of the Committee or Council, and must reach him not later than Monday, December 30th.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of his office, to take charge in the absence of the Medical Superintendent, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order, Town Hall, Manchester. November 22nd, 1929. F. E. WARBRECK HOWELL, Town Clerk.

County Borough of Huddersfield.

PUBLIC HEALTH DEPARTMENT.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Huddersfield invite applications from registered Medical Practitioners for the above appointment.

Candidates should be ladies who are particularly interested in the welfare of mothers and infants, and who are prepared to work wholeheartedly in an intensive scheme for the protection of their health.

Forms of application are not provided.

Candidates should set out their qualifications and experience, and furnish three recent testimonials and/or two references.

The salary will be at the rate of £500 for the first year, and thereafter at the rate of £600 per annum.

Applications should be addressed to S. G. MOORE, M.D., M.R.C.P., D.P.H., Medical Officer of Health, so as to reach him not later than December 9th.

J. HENRY FIELD, Town Clerk.

November, 1929.

County Borough of Blackburn.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners for the post of Assistant Medical Officer (male), who will act under the supervision of the Medical Officer of Health and the School Medical Officer.

The person appointed must devote the whole of his time to the service of the Corporation.

The duties of the office will consist largely, but not exclusively, of work in the School Medical Department.

The salary will be £600 per annum, to be increased by annual increments of £25 to a maximum of £700 per annum; no bonus will be payable.

Forms of application and further particulars of the duties and conditions of the appointment may be obtained from the Medical Officer of Health, Victoria Street, Blackburn.

Completed forms, accompanied by copies of three recent testimonials, must reach me by Saturday, December 14th, and should be endorsed on the envelope "Assistant Medical Officer."

Canvassing will disqualify.

Town Hall, Blackburn. November 18th, 1929. LEWIS BEARD, Town Clerk.

Hampshire County Council.

ASSISTANT COUNTY MEDICAL OFFICER.

Applications are invited for the post of Assistant County Medical Officer. Preference will be given to a woman with experience in maternity and child welfare work, including maternity centres and ante-natal clinics, and in the treatment of venereal diseases. Possession of a Diploma or Degree in Public Health is essential, and previous experience in Public Health work, tuberculosis, and medical inspection of school children will be considered an advantage.

Salary £600 a year, rising by increments to £750 (subject to deductions under the Local Government Officers Superannuation Act), in addition to travelling expenses and subsistence allowances.

Applications, with copies of not more than three testimonials upon a form which, with the conditions of appointment, may be obtained from the County Medical Officer, The Castle, Winchester, should be sent to him not later than December 27th. Canvassing is prohibited.

Lancashire County Council.

BIDDULPH GRANGE ORTHOPAEDIC HOSPITAL.

Applications are invited for the post of JUNIOR HOUSE SURGEON (woman) at the above Hospital, which contains 87 beds. Salary is at the rate of £150 a year, together with board, residence, and laundry.

The appointment will be for a period of six months in the first instance, and for a further period of six months at the option of the Council.

Candidates must be duly qualified and registered. Preference will be given to candidates who have held resident hospital appointments, and who are competent anæsthetists.

Applications, with copies of two recent testimonials, should be sent not later than December 7th to Dr. J. J. BUTTERWORTH, School Medical and Child Welfare Department, County Offices, Preston.

Duties to commence February 1st, 1930.

County Offices, Preston. November 22nd, 1929. GEORGE ETHERTON, Clerk of the County Council.

County Borough of West Ham.

PLAISTOW FEVER HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICER (male) required. Appointment will be for six months. Salary £300 per annum, with residence, board, and laundry. Preference will be given to candidates who have held a resident appointment in a General Hospital. Good facilities for Post-Graduate study.

Applications, with copies of three recent testimonials, to be sent to the Medical Superintendent, Plaistow Fever Hospital, London, E.15.

Edinburgh Hospital for Women AND CHILDREN

WHITEHOUSE LOAN, EDINBURGH.

Applications are invited from qualified Medical Women for the post of HOUSE PHYSICIAN at the above Hospital. The appointment is for six months from January 1st, 1930, with board, residence, and laundry.

Applications, with copies of testimonials, to be received by the Secretary on or before December 16th.

Burgh of Kilmarnock.

MEDICAL OFFICER OF HEALTH.

The Town Council invite applications from duly qualified and registered Medical Practitioners holding the Diploma in Public Health or an equivalent qualification, for the appointment of Medical Officer of Health for the Burgh. Candidates must not exceed 45 years of age.

The person appointed will be required to carry out all the duties pertaining to the position of Medical Officer of Health under the Scottish Burgh Police, Infectious Diseases, Notification of Births, Public Health, Housing, Milk and Dairies, Food and Drugs, Blind Persons, and Local Government Acts, and all other relative Statutes and Orders. The appointment will include the duties of Medical Officer of Kirklandside Infectious Diseases Hospital, Kaimshill Tuberculosis Sanatorium, the Maternity Home and Child Welfare Centre, and the Clinic for the treatment of Venereal Diseases; the duties as Tuberculosis Officer, Police Surgeon, and Medical Officer of Model Lodging House; and, from May 15th, 1930, the duties of the Medical Officer under the Scottish Poor Law, Lunacy and Mental Deficiency, and Vaccination Acts, and all other relative Statutes and Orders. The appointment will also include generally any other responsibility or work (including work in connection with medical inspection and treatment of school children and hospital facilities for the treatment of sick persons) that may be assigned to the Medical Officer of Health by the Town Council either by themselves or in conjunction with any other Public Authority or Body.

The person appointed will be required to devote the whole of his time to the duties of the office, and to reside in the Burgh. He will not be allowed to engage in private practice, and all fees which may be paid to or received by him must be paid over to the Corporation. Applicants should have had previous experience in the various branches of the work.

The inclusive annual salary is £800, and the appointment is subject to the approval of the Department of Health for Scotland. The successful candidate will be required to pass a medical examination.

Copies of the Specification of Duties and Conditions of Appointment may be obtained from the Subscriber, with whom applications (enclosed in envelopes endorsed "Medical Officer of Health"), stating age, qualifications, previous experience and present employment, together with one copy of recent testimonials, should be lodged by December 14th.
